One of the oldest institutions of the kind is the Western Skin Hospital (Welbeck Street, W.), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the "London Skin Hospital," in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the Metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

**LONDON TEMPERANCE HOSPITAL.**—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

**METROPOLITAN HOSPITAL,** Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

**TOTTENHAM HOSPITAL,** N.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

## METROPOLITAN POST-GRADUATE INSTITUTION.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.**—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration, are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, urinary analysis, gynaecology, laryngology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery, bacteriology, and public health.

A complimentary ticket for three days, admitting to *cliniques* and lectures, is issued to any medical practitioner on personal application at the college. The annual subscription for medical practitioners of either sex, holding qualifications granted in any of H.M.'s dominions—wherever resident—is One Guinea. Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S.

**WEST LONDON POST-GRADUATE COLLEGE.**—The West London Hospital, Hammersmith, contains 154 beds; the Post-Graduate course was started in 1895. Instruction is given in the out-patient department daily at 2.15 p.m., by assistant physicians and assistant surgeons, and post-graduates can accompany members of the staff on their daily visits to the wards.

*Fees.*—The fee for the hospital practice, including all the ordinary demonstrations and lectures, is £1 1s. for one week; £2 2s. for one month; £4 4s. for three months; £6 6s. for six months; £9 9s. for one year; and £21 for a life ticket; all fees to be paid in advance.

A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery, is £2 2s.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE.**—At the Tottenham Hospital, N., which is recognised by the University of London for purposes of post-graduate study for the M.D. and M.S. degrees, facilities are afforded to medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations of various branches of medicine, surgery, and gynaecology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, diseases of the skin, and dentistry. Clinical lectures and demonstrations are given twice weekly, and include, in addition to the above, instruction in fevers, tropical medicine, psychological medicine, state medicine, electro-diagnosis, and the administration of anaesthetics. Operations are performed every afternoon of the week, except Saturday. The fee for one month's hospital practice is 2 guineas; for three months', 3 guineas, and for a perpetual ticket, 5 guineas. Post-graduates who have attended a three months' course in any department are eligible for appointment as clinical assistants in those departments. Additional information can be obtained from the Dean at the Post-Graduate College, Tottenham.

## PROVINCIAL MEDICAL SCHOOLS.

**BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.**—The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothe-

caries' Society of London, and for the examination of the Army and Navy Boards. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments, and special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

*Appointments.*—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

*Scholarships, Prizes, &c.*—Prizes and certificates of honour are given in University College in all the subjects of the curriculum. There are two entrance scholarships, value £50 and £30 respectively, two Martyrs' memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbit's memorial prize, value £9, for proficiency in practical surgery, Henry Marshal prize, £12; Clarke Scholarship, £15; Sanders Scholarship, £22 10s.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

*Fees.*—School fees for attendance on all courses of lectures, except comparative anatomy, 70 guineas, or 55 guineas. Dental composition fee, 60 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual medicine and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

**SCHOOL OF MEDICINE, THE UNIVERSITY, Leeds.**—This school was originally founded seventy years since as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened six years ago, contains one of the finest dissecting rooms in the Kingdom, extensive laboratories for physiology and pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken; besides the infirmary there is a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the school.

*Scholarships, Prizes, &c.*—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually. (2) A University scholarship of £25 (awarded annually). (3) An entrance scholarship of 64 guineas. There are also a Hardwick prize in clinical medicine, a McGill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

At the General Infirmary, containing 447 beds, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary.

**MANCHESTER.**—THE MANCHESTER UNIVERSITY SCHOOL OF MEDICINE.—The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

*Appointments.*—The following appointments are made in connection with the Manchester Royal Infirmary:—Surgical registrar, at £80 per annum; a pathological registrar, at £100 per annum; a medical registrar, at £70 per annum; two assistant medical officers, each at £50 per annum; a director of the Clinical Laboratory at £75 per annum; an assistant director of the Clinical Laboratory at £50 per annum; a resident medical officer at the Convalescent Hospital, Cheadle, one year, £150 per annum; resident medical officer, one year, £150; and an assistant at £80 per annum; resident surgical officer, one year, £150 per annum; two chloroformists, annually, at £50; two house surgeons and one house physician are appointed every three months for a term of six months; a resident assistant at the Convalescent Hospital, Cheadle, appointed every six months, and other appointments.

*Scholarships.*—Dalton entrance scholarships, £40 per annum for two years; Cartwright entrance scholarship, £35 per annum for three years; Hulme entrance scholarships, three of £35 per annum for three years; Rogers entrance scholarship, £40 per annum for two years; Seaton entrance scholarship, £40 per annum for two years; James Gaskill entrance scholarship, £40 per annum for two years; Kay Shuttleworth (Sir Jas. Philips) scholarship, £30 per annum for three years; Theodore's modern languages exhibition, £15; Honorary Research Fellowships; Entrance scholarships in Medicine, £100 (towards College and Infirmary fees); Manchester Grammar School scholarships, three of £25 per annum for three years; Turner scholarship of £20 to students who have completed four years of study in the University; Platt physiological scholarships, two of the value of £50 each, tenable for two years, open to students between the ages of 18 and 25; Platt biological scholarship, £50; one Professor Tom Jones exhibition in anatomy of £25; one Professor Tom Jones memorial surgical scholarship of £100, awarded triennially; two Platt exhibitions, £15 each, for first and second year's students in physiology; Sidney Renshaw physiological exhibition, £15; Dumville surgical prize, £15, at the end of the winter session; two Dauntsey medical entrance scholarships, value £35, tenable for one year; John Henry Agnew scholarship in diseases of children, value about £30, awarded annually; a Gilchrist scholarship of £50 per annum tenable for three years, awarded to the candidate standing highest in the first division of the Matriculation examination of the University; the Bradley memorial scholarship, £20, in clinical surgery is offered annually in the summer session to candidates who must be fourth year students; one medical and one surgical clinical prize are also offered annually.

*Fees.*—Composition fee, £70, in two sums of £35 each. Hospital practice: composition fee, £42, or two instalments of £22 each.

*Dental Fees.*—Composition fee, £50, payable in two sums of £25 each. Hospital practice, £21.

**UNIVERSITY OF DURHAM COLLEGE OF MEDICINE,** Newcastle-on-Tyne.—A very commodious and ornate

new building has been erected here at a cost of about £31,000. The Royal Infirmary, at which clinical instruction is obtained, contains 280 beds. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

*Appointments.*—Assistant demonstrators of anatomy receiving each an honorarium; prosectors for the professor of anatomy; assistant demonstrators of physiology and pathology; assistants to the dental surgeon, clinical clerks, and dressers are appointed at regular intervals. One year's attendance at the College is required on the part of candidates for the degrees in medicine of the University of Durham.

*Scholarships, &c.*—University scholarships, value £100, for proficiency in arts, awarded annually at the beginning of winter session to full students in their first year only. The Dickinson memorial scholarship (value, the interest of £400 with a gold medal) for medicine, surgery, midwifery, and pathology, open to full students who have passed the primary examination of a licensing body. The Tulloch scholarship, interest of £400 annually, for anatomy, physiology, and chemistry. The Charlton memorial scholarship, interest of £700 annually, open to full students entered for the class of medicine, at end of the fourth or fifth winter. The Gibb scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder memorial scholarship in clinical medicine and clinical surgery, proceeds of £325 annually. The Luke Armstrong memorial scholarship, interest on £680. The Stephen Scott scholarship in surgery, interest on £1,000. The Heath scholarship in surgery (the next award will be in 1906); the interest on £4,000 is awarded every second year. The Gibson prize in midwifery and diseases of women and children; the interest on £225 is awarded yearly. At the end of the session a prize of books is awarded in each of the regular classes.

*Fees.*—(a) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. (b) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; or by three instalments at the commencement of the sessional year, viz., first year, 12 guineas; second year, 10 guineas; third year, six guineas; or by two instalments, viz., first year, 14 guineas; second year, 12 guineas.

**SHEFFIELD UNIVERSITY COLLEGE MEDICAL DEPARTMENT.**—The medical department contains a medical library, good class-rooms, an excellent anatomical department, and every provision for medical education under the most modern principles. The Favell laboratory of physiology consists of a lecture and demonstration theatre, students' laboratory, preparing room and galvanometer room, all of which are equipped with the most modern apparatus. The pathology department is in a separate temporary building. It contains a pathological museum and laboratory, and a bacteriological laboratory, which has been completely equipped through the generosity of "A Sheffield Citizen." The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Full courses of instruction required for the D.P.H. are given. The dental department is recognised by the examining bodies. Students at this college obtain medical and surgical practice at the Royal Infirmary, containing 247 beds, and also at the Sheffield Royal Hospital, containing 160 beds. The fees for attendance, £6 6s. each for medical and surgical practice during the winter session, and for three months £3 3s. each. Perpetual fee for medical and surgical hospital practice in a single payment of £45, or in two payments, viz., £26 on entrance, and £22 within twelve months

herwards. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women (80 beds), the City Fever Hospitals, and to the South Yorkshire Tubercular Asylum at Wadsley. The winter session will commence on October 3rd. The building of the new college for departments of Arts, Science, and Medicine, is in active progress and will be ready for occupation in October, 1905. The site adjoins Weston Park and is within easy distance of the hospitals.

**Scholarships, &c.**—An entrance scholarship of the value of £110 is annually awarded to the best candidate of sufficient merit in mathematics, elementary physics, inorganic chemistry, Latin, English.

Composition fee, 60 guineas, or in two instalments of 5 guineas and 30 guineas, for lectures and practical classes required by the Examining Board in England.

The Kaye scholarship, for second year's students, natives of Sheffield, is awarded annually, under certain regulations. Prizes for clinical medicine and clinical surgery: prizes in books and certificates awarded annually.

**UNIVERSITY COLLEGE, CARDIFF, SCHOOL OF MEDICINE.**—This college, which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in Materia Medica and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

A course of lectures to midwives, adapted to the requirements of the Central Midwives' Board, under the Midwives' Act, will be commenced early in October, 1904. The lectures will be suitable both for pupil-midwives and practising-midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

**Scholarships, &c.**—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which

may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar.

**LIVERPOOL ROYAL SOUTHERN HOSPITAL.**—The clinical school of this hospital is situated within convenient distance of the Liverpool University, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and in addition to the general medical and surgical cases attention is devoted to the diseases of women and children. There is a special ward for tropical diseases in connection with the University laboratories.

The medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additions have been made to the teaching staff so that students may now obtain instruction in diseases of the eye, ear and throat. Demonstrations in the use of the X-ray apparatus are given at intervals. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for and regular instruction is given in practical pathology. The practice of St. George's Hospital for Diseases of the Skin is free to students, and thus ample opportunity is afforded for acquiring a knowledge of dermatology. In addition to the clinical clerkships which are allotted to the students the resident posts of ambulance officers are given to the students whom the board may think most suited to hold them every three months. The Alexander Fellowship in Pathology of £100 a year is open to students of this school; three prizes of £5 each are also awarded to the gentlemen who present the best taken series of medical and surgical cases. *Fees*: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

There are rooms for a limited number of resident students; terms (exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

**LIVERPOOL SCHOOL OF TROPICAL MEDICINE.**—This school, which has for its object research into Tropical Diseases and Improvement in Tropical Sanitation, was founded in Liverpool in 1899 by Sir Alfred Jones, K.C.M.G., who is the chairman of the school. The research work of the school is carried on at the Johnston Laboratories, in Liverpool University. The clinical work is carried on at the Royal Southern Hospital. A special feature of the work of the Liverpool School of Tropical Medicine has been the despatch of a large number of important medical expeditions to various places in the tropics, especially West Africa. Although the School has only been in existence for a short time it has already sent over a dozen of these expeditions. In addition, the School has issued a number of valuable publications and monographs on subjects connected with tropical diseases, which can be obtained from Messrs. Williams and Norgate. The Duke of Northumberland, K.G., and Mr. William Adamson are Vice-Chairmen of the School, and the following is the Staff:—The Sir Alfred Jones Professor of Tropical Medicine, Major Ronald Ross, C.B., F.R.S., F.R.C.S.; Walter Myers Lecturer, Dr. J. W. W. Stephens, M.D.; Walter Myers Fellow, Dr. J. E. Dutton; Assistant Lecturers, Dr. A. S. Grünbaum, Dr. Fielding Ould, Dr. Balfour Stewart, Dr. H. R. Christy, A. H. Milne, M.A. (Cantab.), Hon. Secretary.

**The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached:—**

**BATH ROYAL UNITED HOSPITAL.**—This is a well-appointed hospital in the West of England, with 130 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months', ten guineas.

**BRADFORD INFIRMARY.**—The hospital contains 230 beds. Non-resident pupils are received—and abundance of clinical material is obtainable. One year's

attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

**BRIGHTON SUSSEX COUNTY HOSPITAL** contains 190 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

**LIVERPOOL NORTHERN HOSPITAL** contains 155 beds. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; practical pharmacy, £2 2s.

**NORFOLK AND NORWICH HOSPITAL**.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

**NORTHAMPTON GENERAL INFIRMARY**.—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

**ROYAL BERKSHIRE HOSPITAL**.—The town of Reading, at which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains a splendid library, in which the Reading Pathological Society holds its meetings.

**THE ROYAL HOSPITAL, PORTSMOUTH**.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognised by the Examining Boards. The number of beds is 150. The fees being the same as at all similar institutions.

**ROYAL DEVON AND EXETER HOSPITAL, Exeter**.—The hospital contains 218 beds (including special children's wards), and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards. Arrangements can be made by which students can attend midwifery on application to the House Surgeon.

**WOLVERHAMPTON GENERAL HOSPITAL**.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. Fees: Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

#### THE ENGLISH UNIVERSITIES.

The English Universities are eight in number, viz., Oxford, Cambridge, London, the Victoria, Durham, Liverpool, Leeds and Birmingham. The choice of a University is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial universities.

#### OXFORD.

There are two degrees in medicine, B.M. and D.M., and two degrees in surgery, B.Ch. and M.Ch. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the second (B.M.) examination. Graduates in Arts, B.A., are alone eligible for these degrees. In order to obtain the degrees of B.M. and B.Ch., the following examinations must be passed:—1. Preliminary: Subjects:—

Physics, chemistry, zoology, and botany. 2. Professional (a) First examination (held twice a year): Subjects:—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy; Materia medica with pharmacy. (b) Second examination: Subjects:—Medicine, surgery, midwifery, pathology, forensic medicine with hygiene. The approximate dates of the examinations are as follows:—Preliminaries:—Physics, and chemistry, December and June; Zoology and botany, December and March; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University who have entered on their thirty-ninth term on their presenting a dissertation approved of by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June.

The First examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be offered and passed together.

In the Second Examination candidates are allowed to present themselves in Pathology, and also in Forensic Medicine at separate Examinations at any time after the First Examination has been passed; but no candidate is permitted to enter for the Examinations in Medicine, Surgery, and Midwifery until he has attained the twenty-fourth term from his matriculation—i.e., six years.

*Diploma in Public Health*.—An examination is held yearly in Michaelmas Term. The first part comprises the application of Chemistry and Physics to General Hygiene. The second part comprises the following subjects:—General Pathology, with special relation to Infectious Diseases; the Laws relating to Public Health; Sanitary Engineering; Vital Statistics. Both parts may be taken together at the same Examination, or they may be taken at separate Examinations: but no one is deemed to have satisfied the Examiners in Part II. unless he has satisfied the Examiners in the subjects of Part I. A diploma is issued to every candidate who has passed in both parts of the Examination, but no Diploma or Certificate is given under any other circumstances. Candidates must have their names on the "Medical Register" and must have satisfied all the Rules of the General Medical Council of the United Kingdom relating to the admission of Candidates for Diplomas in Public Health which are in force at the time.

More detailed information may be obtained from the "Examination Statutes" with the "Regulations" for the current year, published annually in June at the Clarendon Press Depot, price 1s.

#### CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry and physics, and (2) biology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first and the third examinations are divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination

for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University degree grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

#### UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the students are divided into "Internal" and "External." An internal student is one who has matriculated at the University and is studying in a school approved by that body, or under the teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat in their application to the two groups of students. We only propose to deal with them as they affect *internal* students, since the special information required by the others had best be obtained direct from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least three years has elapsed since matriculation or other examination entitling to registration as a medical student.\*

The *Matriculation Examination* will take place three times in each year—in January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 16th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which *must* be English and elementary mathematics. The other three (one of them a language) may be selected from the following:—Latin, Greek, French, German, Arabic,\* Sanscrit,\* Spanish,\* Portuguese,\* Italian,\* Hebrew,\* Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced than in the compulsory examination), Elementary Mechanics, Elementary Chemistry, Elementary Biology

\* May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment

(Botany), Elementary Biology (Zoology),\* Elementary Physics, Heat, Light, and Sound, Electricity, and Magnetism. Candidates who desire to be examined in the subjects against which an asterisk is affixed must give at least two months' notice.

The *Preliminary Scientific Examination* will take place twice in each year, in January and July. It will consist of papers in chemistry, biology, and physics, and there will be a practical examination in each subject. Examiners will also be at liberty to test candidates *viva voce*. A student may present himself for examination in each of the three subjects, separately or in all at the same time. Part I. of this examination includes papers in inorganic chemistry, physics, and biology, with practical examinations; Part II. is an examination in organic chemistry.

The *Intermediate Examination in Medicine* will take place twice a year, January and July. Candidates must have passed the Preliminary Scientific Examination at least two years previously. The subjects of examination are Anatomy, Physiology and Histology, and Pharmacology, including *Materia Medica*. Candidates who have failed in one subject only at this examination may offer themselves for re-examination in that subject, if permitted to do so by the examiners. Three scholarships, one of the value of £40 in Anatomy, another of the same amount in Physiology, and one of £30 in Pharmacology may be awarded by the examiners to any candidate who has passed the whole of the examination at one time.

The *Final M.B., B.S., Examination* will take place twice a year, in October and May. No candidate will be admitted to this examination unless he has completed the course of study prescribed in the schedule or in less than two academic years from the date of passing the Intermediate Examination in anatomy and physiology.

The subjects of the examination are Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, and Midwifery and Diseases of Women. The subjects may be divided into two groups, one of which shall comprise Medicine, Pathology, Forensic Medicine and Hygiene; and the other Surgery, Midwifery and Diseases of Women. Either group may be taken first at the option of the candidate, or the groups may be taken together.

Only candidates who show a competent knowledge of all the subjects comprising a group will be passed. The examiners will be empowered to recommend the award of a University Medal to the candidate who has most distinguished himself in the whole examination.

*Doctor of Medicine.*—The examination for the degree of Doctor of Medicine will be held twice in each year, in December and July. Every candidate must have passed the examination for the M.B., B.S., of this University. Candidates may present themselves for examination in one of the following branches: (1) Medicine, (2) Pathology, (3) Mental Diseases, (4) Midwifery and Diseases of Women, (5) State Medicine; and if they wish, may pass also in another branch at a subsequent examination. Candidates for Branches 1 to 4 who have taken honours at the M.B., B.S., examination in the subject in which they present themselves for the M.D. degree, or who, subsequently to taking the M.B., B.S., have conducted a piece of original work approved for the purpose by the University, or have had special experience approved by the University, may present themselves for the M.D. examination one year after taking their Bachelor's

of £2: Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have passed all the examinations required for a degree in those Universities, also women who have obtained Tripos certificates granted by the University of Cambridge, and women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations at Oxford, they have passed the Second Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who hold the Scotch School Leaving Certificate, having passed on one and the same occasion, in the Higher or Honours Grade in all the subjects required by the regulations for the Matriculation Examination, and those who hold the Zeugnis der Reife from a Gymnasium or Realgymnasium within the German or Austrian Empire, or the Maturitäts-Zeugnis of a Swiss Gymnasium or Oberrealschule, or the Eidgenössische Maturitäts-Zeugnis of Switzerland.

degree. Other candidates must show that they have taken the degree of M.B., B.S., not less than two years previously; and as regards candidates in Branches 1 to 4, that subsequently to taking that degree they have held for at least six months a resident or non-resident medical hospital appointment, or that they have been in qualified practice for not less than five years, while candidates in Branches 2 and 3 must show that they have held in the one case a pathological and in the other an asylum appointment. In each branch there will be (1) two papers on the special subject of the branch; (2) a clinical examination; (3) an essay to be written on one of two given subjects connected with the branch. In Branch 1 there will also be a paper on pathology, and in Branches 2, 3, and 4 a paper in medicine, while in Branch 2 a laboratory examination will be substituted for the Clinical Examination held in the other branches.

Candidates in Branch 5 (State Medicine) must show that they have taken the degrees M.B., B.S. not less than two years previously, and that subsequently to taking those degrees they have had (1) six months' practical instruction in an approved laboratory; (2) six months' practical instruction from a medical officer of health, of which three must not coincide with the laboratory work, and three months' practice at a hospital for infectious diseases. The interval between passing the M.B., B.S. and proceeding to the M.D. State Medicine may be reduced to one year, subject to conditions corresponding to those affecting Branches 1, 2, 3, and 4.

*Master of Surgery.*—The examination for the degree of Master in Surgery will take place twice in each year, commencing on the same dates as the foregoing, and the general regulations already quoted with regard to the M.D. will practically apply to it, surgery being substituted for medicine. The examination will consist of (1) two papers on surgery (one of which may be a case for commentary); (2) an essay to be written on one of two subjects which may be selected from any branch of surgery; (3) two papers on surgical pathology and surgical anatomy; (4) a clinical examination; (5) operations on the dead body; (6) a *viva voce* at the discretion of the examiners. Competent knowledge in every subject of the examination must be shown in order to pass.

For the M.S. degree and all branches of the M.D. a candidate is at liberty to forward a thesis or copies of published works embodying the result of independent research in the subject in which he presents himself for a degree and also any printed contributions to the advancement of professional knowledge published either separately or conjointly. If the examiners consider such thesis or works of sufficient merit they are empowered to exempt a candidate partly or entirely from examination in the subject to which such work refers. They also have power to award a University Medal to the candidate who at the examination in any branch passes with most distinction.

*Fees.*—For the Matriculation: £2 and £1 on re-examination in any one subject, and £2 for more than one. Preliminary Scientific Examination: £5 for each entry to the whole examination, and £2 for each subject when less than the whole examination is taken at one time. Intermediate Examination: £10 for each entry to the whole examination, and £5 for examination in one subject. M.B., B.S. Examination: £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations: £20 for each entry.

#### UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, *viz.*, the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medi-

cal jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice.

Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examination of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course or regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must prepare an essay, which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1904-5.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

#### VICTORIA UNIVERSITY OF MANCHESTER.

Candidates for degrees in medicine and surgery must attend classes in the University during at least two years.

The degrees in the Faculty of Medicine are Bachelor

of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in medicine and surgery are required to pass the Matriculation Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Matriculation Examination are—1, Latin; 2, mathematics; 3, mechanics; 4, English and history; 5, one of the following:—(a) French; (b) German; (c) Greek; (d) Italian; (e) Spanish; (f) any other modern language, permission to present which has been obtained from the Joint Matriculation Board. Notice of intention to present either Italian or Spanish must be given to the Secretary, Joint Matriculation Board, Manchester, before March 1st in each year.

Before admission to the degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities.

All candidates for these degrees must pass three examinations, namely—the First Examination; the Second Examination; and the Final Examination.

**First Examination.**—The subjects of the examination are, 1, Chemistry; 2, Elementary biology; 3, Physics.

Candidates must have attended, during at least one year, courses of both lectures and laboratory work in each of the above-named subjects.

**Second.**—1, Anatomy; 2, Physiology (including physiological chemistry and histology); 3, Materia medica and pharmacy.

Candidates must have passed the First Examination, and have attended courses of instruction in anatomy (systematic and practical) during two winter sessions and one summer session, in physiology for two winter sessions, in materia medica and pharmacy for one summer session. Candidates may present themselves separately in (a) anatomy and physiology, (b) materia medica and pharmacy.

**Final.**—The examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B., or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

**Fees.**—Matriculation examination, £2; for any subsequent examination, £1. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Final Examination, and for the examination for the degree of Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Matriculation Examination is held in June, in July (for schools), and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The Second and Final Examinations are held in March and July, the examination for Ch.M. in July only.

#### UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain

any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

**Degrees of Bachelor of Medicine and Bachelor of Surgery.**—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge; (b) Responsions of the University of Oxford; (c) The matriculation examination of any other University in the United Kingdom; (d) The leaving certificate (higher) of the Oxford and Cambridge Boards; (e) The Oxford or Cambridge junior local examination (first or second class honours); (f) The Oxford or Cambridge senior local examination (honours); (g) The College of Preceptors examination for first-class certificate.

Matriculation Examinations are held in June and September each year.

**Degrees of Doctor of Medicine and Master of Surgery.**—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Registrar. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

**Dental Department.**—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.) The whole of the instruction for which may be taken out in the University.

**THE GENERAL AND QUEEN'S HOSPITALS.**—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 6,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Windle, Dean, Medical Faculty.

#### UNIVERSITY OF LIVERPOOL.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees and qualifications of the other licensing bodies.

**Hospitals.**—Students may take out their clinical work at the Liverpool Royal Infirmary, or at the United Hospitals Clinical School, which has been formed by the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital. Particulars as to fees, appointments, &c., may be obtained from the Secretaries of these schools. The practice of the Lying-in, Eye and Ear, Women's, Children's, Dental, and Skin Hospitals is also open to students of the Faculty of Medicine.

**Fellowships and Scholarships.**—Fellowships, Scholarships, and Prizes of over £700 are awarded annually. A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the Pathological department. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnson Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynaecological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatological Pathology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical

Pathology. Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1904 the subject will be Clinical Medicine. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, the Robert Gee Book Prize, of the value of £5, for Children's Diseases, and numerous class prizes are awarded annually.

*Entrance Scholarships.*—Four Robert Gee Entrance Scholarships, of the value each of £25 for one year, are offered annually for competition. The holder is required to take out the Science Course for the University Degree in Medicine.

Communications should be addressed to the Dean, Professor Benjamin Moore, M.A., D.Sc., the University, Liverpool.

### THE ENGLISH COLLEGES.

THE medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

#### CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and biology, to comply with the following regulations and to pass the examinations hereinafter set forth.

*Professional Examinations.*—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates.

The subjects of the first professional examination are chemistry and physics, practical pharmacy, and elementary biology. A candidate is allowed to take this examination in three parts at different times. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the

expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynaecology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s.

Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynaecology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

#### REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

*Licentiate.*—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

The following by-laws, amended in conformity with the revised regulations of the Conjoint Examining Board, were re-enacted as follows:—

"Every candidate for the College licence (unless specially exempted) shall be required to produce satisfactory evidence of having passed before the commencement of professional study a preliminary examination on subjects of general education recognised by the College.

"Every candidate shall be required to produce satisfactory evidence of having completed five years of professional study, after passing a recognised preliminary examination before admission to the final examination.

"A candidate shall not be admitted to the second examination until the completion of two winter sessions and one summer session (or 15 months during the ordi-

nary sessions) at a recognised medical school, nor until the expiration of one winter and one summer session after passing Parts I. and III. of the first examination.

"A candidate shall not be admitted to the third (or final) examination till the expiration of five winter and five summer sessions from the date of passing the preliminary examinations and of four winter and four summer sessions after passing Parts I. and III. of the first examination, and of two winter and two summer sessions after passing the second examination."

**Members.**—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 5s. is deducted. In either case £6 6s. has to be paid before examination.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

**MEMBERSHIP.**—The candidates are now subject to the regulations of the Conjoint Board.

**FELLOWSHIP.**—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

**FEES.**—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final. The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

#### SOCIETY OF APOTHECARIES OF LONDON.

**PRIMARY EXAMINATION.**—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (a) The Principles and Practice of

Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts.

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

**FEES.**—Primary examination, £10 10s.; final examination, £10 10s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

## Ireland.

### THE IRISH MEDICAL SYSTEM.

THE system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to resort to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is free to do as he pleases.

#### BOARD AND RESIDENCE.

There is in Dublin no organisation for domestic accommodation of medical students, save for those who are passing through Trinity College, in whose case rooms and "commons" (*i.e.*, dinner) are provided at fixed rates. Those who can afford to pay £6 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man who receives boarders, in which case they become members of the family for the time being. The majority of Dublin students, however, take a lodging in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves.

#### COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this

connection the following tables may be of use to the prospective student :—

COST OF MEDICAL EDUCATION.	
School of Physic, Dub. Univ. . .	£119 14s.
Royal College of Surgeons School . .	£124 19s.
Catholic University School . .	£124 19s.
Queen's College . . . . .	About £110
COST OF DIPLOMAS OR DEGREES.	
Dublin University : . . . .	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University . . . . .	£15.
Conjoint Royal Colleges . . . .	£42.
Apothecaries' Hall . . . . .	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £229 18s., according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding" usually costs £5 5s. for each of the four examinations, but if a student needs private instruction in special subjects he must pay extra for it.

This sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion. If, on the other hand, he prefers to pay a large sum down, he can "apprentice" himself to a teacher who will undertake all monetary responsibility for his education, and who may be able to give him some special advantage as his own pupil at hospital. This so-called "apprenticeship," is very generally a simple contract for the payment of fees, and involves but little special teaching. All the Dublin schools require fees to be paid in advance.

#### DATE OF ENTRY.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be recollected that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

#### PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Education passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the

General Medical Council are as follows :—1. English language, including a specified author, dictation, grammar, and composition ; also parsing and analysis from the book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions ; (b) algebra, including simple equations ; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects :—(a) Greek, (b) French, (c) German.

#### QUALIFICATION IN IRELAND.

The Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes :—a. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. b. Those who take the licence of the conjoint Royal Colleges of Physicians and Surgeons. c. Those who take the licence of the Apothecaries' Hall. d. Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. e. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows :—

#### THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the grade of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows :—Lectures, £64 11s. 6d. ; Hospitals, £55 13s. ; Degree Fees, £27.—Total, £147 4s. 6d.

The expense of the B.A., amounting altogether to £83 4s., should be added, making the total cost £230 8s. 6d.

In addition to its ordinary qualifications the University grants the following higher degrees :—

*Doctor of Medicine.*—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Total fee for this degree, £13.

*Master of Surgery.*—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for degree, £11.

*Master in Obstetric Science.*—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects :—Practice of midwifery, gynaecology, anatomy of female pelvis and elementary embryology, and clinical gynaecology. Fee for this degree, £5.

*Diplomatic in Medicine, Surgery, and Midwifery.*—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in

**Medical studies.** The course and examination is the same as for the degrees, except that the lectures and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not have obtained an Arts degree. Fee for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the lectures on botany and zoology, passing the previous medical examination in those subjects, and paying the degree fees.

**Diploma in Public Health.**—The candidate must be an M.D. of Dublin, Oxford, or Cambridge, must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months, under an approved Officer of Health (*v.* also page 286.).

#### THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, *i.e.*, the matriculation examination of this University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B., B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., and M.A.O. It also confers a diploma in sanitary science and a diploma in mental diseases.

All degrees are open to persons of either sex.

The University examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about October 1st.

All candidates for any degree must pass the matriculation examination and the first University examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first University examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2; for the diploma, £10.

In addition, the following degrees are granted:—**Diploma in Sanitary Science.**—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. **Subjects.**—Climatology, chemistry, geology, physics, vital statistics, hygiene, sanitary law.

**The M.D. Degree.**—Conferred only on graduates in medicine of the University of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. Fee, £5. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom.

**The M.Ch. Degree.**—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. Fee, £5.

The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology.

**The Mastership of Obstetrics.**—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. Fee, £5.

The examination comprises midwifery and diseases of women and children.

**Prizes, &c.**—First examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

**Second Examination in Medicine.**—Two first-class of £25, and two second-class of £15, and the Dr Henry Hutchinson, Stewart Medical Scholarships, value £10.

The Henry Hutchinson, Stewart Medical Scholarships in psychological medicine, diseases of the nervous system, and anatomy, physiology and pathology of brain, cord, and nerves. Competition among medical graduates of not more than two years' standing. Fee £2.

**Third Examination in Medicine.**—Two first-class exhibitions of £30 each, and two second of £20 each.

**Medical Degrees Examination.**—Two first-class exhibitions of £40 each, and two second of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

#### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

The examinations held conjointly by the two Colleges are the inlet of most Irish students to the profession, especially of those educated in Dublin. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In common with the English Colleges, the subjects of the First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice are required from candidates for the Professional examination.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 286.

#### ROYAL COLLEGE OF PHYSICIANS.

This College issues a licence in Medicine and a licence in Midwifery to registered medical practitioners.

The subjects of examination for the former qualification are:—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene and therapeutics.

The candidate for the licence in Midwifery must produce certificates of having attended a course of lectures on midwifery, and of having attended practical midwifery and diseases of women for six months, at a lying-in hospital or maternity recognised by the College; or, where such hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment, the certificate in either case to state that at least twenty labour cases have been actually attended. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

**Fees.**—Fee for the licence to practise medicine, £15 15s. Fee for examination for the licence to practise midwifery, £3 3s.

**Membership.**—The Examinations for Membership are held in January, April, July, and October.

#### ROYAL COLLEGE OF SURGEONS.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothe-

caries' Society of London, granted since October, 1886, are admitted to examination without further evidence of study, but candidates who hold medical qualifications only, including the L.S.A. granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s. The fee for a special examination is £31 10s.

A diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (a) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (b) attendance on six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (c) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

*Fellowship.*—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. Examinations are held the third Mondays in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination (except during the months of August and September) if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery, surgical anatomy, and surgical pathology.

*Fees.*—Grade 1.—For Licentiates of College; Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

#### APOTHECARIES' HALL OF IRELAND (L.A.H.).

This body is authorised to grant a complete qualification in medicine, surgery, and midwifery, recognised and registrable under the Medical Act of 1886, and entitling the holder to occupy medical appointments in all the public services. It also confers the legal right to dispense medicines. The examinations are held on the third Monday in January, April, July, and October, and the requirements in respect of studies are approximately the same as those of the Conjoint Examinations of the Royal Colleges of Physicians and Surgeons in Ireland. The examination fees payable for the qualifications of L.A.H. are as follows:—First professional, £5 5s.; second, £5 5s.; third, £5 5s.; Final examination, £6 6s.

The fees for re-examination are £1 1s. for each subject, excepting in the subjects of chemistry, medicine, surgery, and ophthalmology, the fees for which are £2 2s.

The fee for final alone is £15 15s., when the other examinations have been taken elsewhere. Candidates may be admitted to a special examination under special circumstances, at an extra fee of ten guineas.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers

dates more than fifteen days prior to such registration. This registration is not undertaken by the Hall, but the student must apply to the Registrar of the General Medical Council that he may be so entered. The details of the course of education required and syllabus of the examinations will be supplied an application to the Registrar at 40 Mary Street, Dublin.

Candidates already on the "Register" will receive the diploma of the Hall on passing an examination in pharmacy and paying a fee of ten guineas. If medicine or surgery should be required two guineas extra will be charged. The candidate will be exempt from each of the above subjects, which are covered by his previous qualification or qualifications.

#### LICENCE IN DENTAL SURGERY.

THERE is probably no speciality in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The University of Dublin grants both a Degree and a Licence in dental surgery. To obtain the former, candidates must have taken a degree in arts; the licence is obtainable by all duly qualified persons who have passed the Public Entrance Examination of Trinity College, Dublin. The Royal College of Surgeons in Ireland grants a Licence in Dentistry.

*Course of Study for the Licence in Dentistry.*—Candidates are required to pass three examinations, viz.:—Preliminary (in General Education), Primary Dental, and Final Dental.

All information concerning this licence may be obtained from the Registrar of the College. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The subjects of examinations include physics, chemistry (including metallurgy), anatomy, physiology and histology, and surgery. The fees for the primary Dental Examination amount to £10 10s.; and for re-examination, if rejected, £5 5s. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are examined in dental surgery, theoretical (including dental pathology), clinical, and operative; and in dental mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

The fees for the Final Dental Examination in the case of candidates holding L.R.C.S.I., or students who have passed Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. The fees for Final Examination of all other candidates, £26 5s., and for re-examination, £10 10s. The extra fee for Special Examination, £5 5s. A rejected candidate will not be again admitted to examination until after a period of three months.

#### THE DIPLOMA IN PUBLIC HEALTH.

THIS diploma is granted by Dublin University, the Royal University, and the conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candidate for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must have been on the "Medical Register" for at least twelve months before the examination. The

Royal University only confers its diploma on its own graduates.

#### THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Royal University of Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions:—

The diploma is conferred only on graduates in medicine of the University. Candidates must give notice, in writing, to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination. Candidates who satisfy the examiners will be required to pay a further fee of £3 before the diploma is conferred. The subjects for this examination are those required by the Hutchinson Stewart Scholarship for proficiency in the treatment of mental diseases.

#### THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

**THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.**—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Every student of the school must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June "Half M.B." Examination in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

**Fitz-Patrick Scholarship.**—This scholarship consists of the interest on £1,000. It will be awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

**THE ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOLS OF SURGERY.**—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for nearly a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the

most modern methods of instruction. A refreshment room is now open, where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes, and lighted throughout by the electric light.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

The diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

**Prizes.**—The Barker Prize, £21; the Carmichael Scholarship, £15; the Mayne Scholarship, £15. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

**THE CATHOLIC UNIVERSITY SCHOOL** is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £12 10s.; one final Conjoint Colleges' Exhibition of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

#### THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

#### QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital. The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and

Throat Hospital, and the District Lunatic Asylum are also open to students.

*Prizes.*—(1) Ten medical scholarships each year, value £20 each; (2) two Dunville studentships (one each alternate year), value £150 each; (3) one Andrews studentship each alternate year, value £140; (4) numerous sessional prizes.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathological laboratories. From time to time lectures and demonstrations are given in the anatomical department on the Advanced Anatomy of the Nervous System, or some other department of applied anatomy.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

#### QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmaries. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 27th, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

*Scholarships and Prizes.*—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of about £32, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

#### QUEEN'S COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital is also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

*Prizes.*—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine, from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close, of each session.

#### THE PHARMACEUTICAL SOCIETY OF IRELAND.

The Pharmaceutical Society of Ireland issue two qualifications and a certificate. The qualification of Registered Druggist; the qualification of Pharmaceutical Chemist; and the certificate of competency as Assistant to a Pharmaceutical Chemist.

*Registered Druggist.*—This qualification entitles the holder to keep open shop for the selling, retailing, and mixing of poisons. In order to obtain it, a person must now have served an apprenticeship or assistantship of four years to an apothecary, pharmaceutical chemist, or to a person who was, or would have been entitled to become, a registered chemist and druggist or a registered druggist, and be 21 years of age. He shall be examined with respect to his knowledge of English orthography and composition, arithmetic, and the weights and measures of the British Pharmacopœia, the appearance and properties of the various drugs and chemicals in general use, and as to the provisions of the Poisons Act. The fee is four guineas.

Examinations in Dublin (also in Belfast and Cork or other place if 12 candidates offer) on the second Tuesday of January, April, July, and October.

*Pharmaceutical Chemist.*—The qualification of a pharmaceutical chemist in Ireland confers greater privileges than is the case in England.

The subjects of examination are divided between the "Preliminary" and the "Licence."

The Preliminary examination is held on the first Thursday and following day of January, April, July, and October.

The fee is £2 2s. for the first attempt, and 10s. 6d. for each subsequent examination. Further particulars with reference to the subjects for examination may be obtained from the Registrar. The British Society's examination is accepted in lieu of this, as well as those recognised by the General Medical Council as a preliminary to medical studies.

*Pharmaceutical Licence Examination.*—This examination confers the title of Pharmaceutical Chemist and the right to compound medical prescriptions. Candidates must be 21 years of age, and must have passed the Preliminary at least a year previously. They must, unless having passed the Preliminary previous to 1884, produce certificates of having served four years as assistant or apprentice to an apothecary or pharmaceutical chemist or four years to a druggist, two years to an apothecary or pharmaceutical chemist, also a certificate of having attended a course of practical chemistry of not less than three months' duration, and of having actually worked at the bench for 100 hours during the said course at a recognised school; and also a course of botany and materia medica. The fee for examination is five guineas, and for re-examination a guinea and a half. Examinations are held in Dublin on the second Wednesday and following day of January, April, July, and October.

*Assistant to a Pharmaceutical Chemist.*—The examination for the certificate of competency as an assistant may be described, in brief, as the same as that for the Licence, minus the examination in chemistry and botany, with the fee reduced to one guinea (half a guinea on the second and subsequent attempts). The Preliminary examination must be passed as for the Licence, and the usual 14 days' notice must be given. Candidates must have been engaged in practical pharmacy for four years.

Examinations are held on the second Mondays of February, May, August, and November, or on such days as the Council may direct.

#### DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

##### ROYAL COLLEGE OF SCIENCE FOR IRELAND.

SESSION 1904-1905.

This College, situate in Stephens Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of agriculture, chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (a) in agriculture, (b) in science and technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable

for two years. Two are competed for by the associate students at the end of each session. The chemical, physical, zoological and botanical, geological and mineralogical laboratories and drawing schools are open daily for practical instruction. The Session commences on Tuesday, October 4th.

The courses of chemistry, physics, botany, geology, and mineralogy and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

#### THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, *i.e.*, three winter sessions of six months and three summers of three months, with the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £6 6s., or £12 12s. for the entire session of nine months if taken together.

#### GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. These hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are very large ophthalmic, aural, throat, and gynecological dispensaries, and instruction in these important subjects is given. Six resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected annually, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoin these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every six months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. Conway Dwyer, F.R.C.S., 9 Rutland Square, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children.

Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. Three resident pupils are selected half-yearly and two house surgeons annually. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15 Stephens Green North.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital has recently been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with the most modern surgical requirements. A Röntgen-ray and light treatment of lupus department has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Full particulars can be had on application to Mr. G. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in these departments during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease.

MATER MISERICORDIÆ HOSPITAL.—This hospital, containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynecology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical and surgical diseases, accidents, &c. Leonard

Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

**MERCER'S HOSPITAL.**—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32 Lower Baggot Street, Dublin.

**ST. VINCENT'S HOSPITAL** was established in 1834, it has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Dr. Tobin, Stephens Green.

**DR. STEEVENS' HOSPITAL**, situated at Kingsbridge, is one of the oldest and largest of the clinical hospitals in Dublin, and contains over 200 beds. Recently, a very fine Nurses' Home has been added to the institution, with accommodation for over seventy nurses. And a new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

**JERVIS STREET HOSPITAL** is the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. Gold and silver medals are given after examinations held at the close of the summer session.

Students of the hospital will get special instruction in the diseases of children and orthopaedic surgery at the Children's Hospital, Temple Street. This will meet the requirements of the R.U.I.

#### SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Throat Hospital, the Orthopaedic Hospital, the Children's Hospitals in Harcourt Street, and in Temple Street, and the City Hospital for Diseases of the Skin.

**THE ROTUNDA HOSPITAL.**—This institution is the largest, the longest established, and the most famous gynaecological as well as maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. More than 2,000 patients per annum are admitted to the maternity wards, over 2,700 per annum are attended in the extern maternity department. The patients attending in the out-patient department number over 14,000 per annum. Daily clinical lectures, operations, and practical instruction in midwifery, gynaecology, and cystoscopy are delivered between the hours of 10 and 1 a.m., and a special afternoon class in gynaecology is held by the senior assistant. The new pathological laboratory, under the direction of Dr. Neville, has become an important feature of the hospital. The hospital affords exceptional advantages to qualified men who desire to take out post-graduate courses in practical work. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies, and the hospital certificate is acknowledged by the Local Government Board as a full legal midwifery qualification. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynaecology is given to students whose work meets with the Master's approval. Paid clinical assistants are selected (from among those who have obtained the hospital certificate) by competitive examination for periods of six months. The residents' quarters have recently undergone complete renovation, and afford comfortable accommodation.

**COOMBE LYING-IN HOSPITAL.**—This hospital, which has been rebuilt and considerably enlarged, and contains 70 beds, was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1867; it is situated in the centre of a district densely populated by the poorest of the community, and thus affords the amplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than 2,000 in number. Moreover, the gynaecological hospital for the reception of cases of the diseases peculiar to women gives admission to nearly 300 patients annually. A new wing for gynaecological cases has been added. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as intern pupil. During that period, the pupil attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. A clinical clerkship is obtainable half-yearly by all pupils who have obtained their midwifery diploma from the hospital, and special certificates are given. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. Nurses who take out the usual hospital course of six months receive special instruction in midwifery, and can obtain their diplomas at the termination of the course, on passing the examination.

**\* NATIONAL MATERNITY HOSPITAL.**—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

**SIR PATRICK DUN'S MATERNITY.**—This is a branch of Sir P. Dun's Hospital, and is under the management of the King's Professor of Midwifery in Dublin University.

The department is at present in process of being re-organised.

**CORK STREET FEVER HOSPITAL** is the only special fever hospital in Dublin. It is supported mainly by an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer session to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

**THE NATIONAL CHILDREN'S HOSPITAL** for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

**THE CHILDREN'S HOSPITAL, DUBLIN** (under the care of the Sisters of Charity).—This institution is one of the most progressive and up-to-date children's hospital in the Kingdom, besides being the largest in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. During the last year a new operating theatre has been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery, and the number of deformities from all parts of Ireland treated and cured in the hospital is rapidly increasing. A special masseuse has been appointed to the hospital to aid in this department. A convalescent home for the institution has recently been acquired at Rahomy; twenty beds are available. While situated in the country, it is within very easy reach of the sea, and during the summer the children are brought daily to the sea-side.

The hospital is recognised for clinical instruction in the diseases of children by the R.U.I. and licensing bodies, which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to H. C. Mooney, hon. sec., or to any member of the staff.

**THE INCORPORATED ORTHOPÆDIC HOSPITAL, IRELAND.**—This hospital was founded in 1876, and contains 70 beds. It is available for every class of deformity available for treatment. Particulars may be obtained from Captain Borthistle, Registrar, at the hospital, or from R. L. Swan, F.R.C.S.I., 32 Stephen's Green.

**THE ROYAL VICTORIA EYE AND EAR HOSPITAL, Adelaide Road, Dublin.**—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Instruction in aural surgery is also given. Special classes for practical instruction in the use of the ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

**THE INCORPORATED DENTAL HOSPITAL, Lincoln Place.**—This handsome hospital, recently erected, is the only special Dental Hospital in Dublin. It is officered by a very strong staff of the leading dental surgeons of Dublin, and has a large *clinielle* and extensive practice among the Dublin poor. The fees are £15 15s. for the first year's study, and £12 12s. for second, and proportionately smaller fees for shorter periods.

**THE CITY HOSPITAL FOR DISEASES OF THE SKIN AND CANCER, Great Brunswick Street.**—The first and only one of its kind in the city was the first in Ireland to instal the Finsen treatment. Senior students are admitted free to the practice of this hospital, which has a large daily out-patient attendance. Classes of instruction will be given at regular intervals during the

winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances and rectifiers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work. Fluorescent screen, and how to localize foreign bodies.

#### BELFAST HOSPITALS.

\* **HOSPITAL FOR SICK CHILDREN, Queen Street.**—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. The convalescent home, which is situated at Newtownbreda, contains thirteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

\* **MATER INFIRMORUM HOSPITAL.**—Established 1883. 160 beds.

**THE BELFAST MATERNITY HOSPITAL (INCORPORATED).**—Established 1794. 16 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by the Royal University, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. Conditions for such on application to the Matron. During the year 1903, 326 patients were treated in the hospital, and 304 patients at their own homes. Besides this, 458 patients were dealt with in the extern gynæcological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, on or before November 1st and May 1st.

**OPHTHALMIC INSTITUTION AND EYE AND EAR HOSPITAL, Great Victoria Street, Belfast.**—Established 1844. New hospital erected, 1867. New extern department and operation theatre added, 1902. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday, and Friday at noon for eye cases, and on Monday and Thursday at noon for ear and throat cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 18 College Square East, Belfast.

**ROYAL VICTORIA HOSPITAL.**—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17, 1903. 300 beds; Convalescent hospital, 24 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

**ULSTER EYE, EAR, AND THROAT HOSPITAL.**—Established 1871. New hospital opened 1874. 30 beds.

\* **ULSTER HOSPITAL FOR CHILDREN AND WOMEN, Mountpottinger, Belfast,** is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working-class district, and has a great field for its charitable operations. There are in the hospital about twenty-two

beds for children and eight for women. There is an extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 11.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Saturday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

#### CORK HOSPITALS.

VICTORIA HOSPITAL FOR WOMEN AND CHILDREN.—Established 1874. 70 beds.

\* COUNTY AND CITY OF CORK LYING-IN HOSPITAL.—Established 1798. 17 beds.

\* EYE, EAR, AND THROAT HOSPITAL, Western Road.—Incorporated 1898. 35 beds.

\* FEVER HOSPITAL AND HOUSE OF RECOVERY.—Established 1801. 110 beds.

\* MATERNITY.—Established 1872.

\* MERCY HOSPITAL.—Established 1857. 80 beds.

\* NORTH CHARITABLE INFIRMARY.—Established 1774. 110 beds.

CORK SOUTH INFIRMARY AND COUNTY HOSPITAL.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

The operation and sterilising rooms are thoroughly up to date. The X-ray department is fully equipped with the newest apparatus necessary for such work. Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

The hospital has been largely availed of by students of the Cork School of Medicine.

#### GALWAY HOSPITALS.

\* COUNTY HOSPITAL.—Established 1786. 60 beds.

\* No answer to our request for information received from these hospitals.

#### IRISH PUBLIC SERVICES.

##### THE POOR-LAW MEDICAL SERVICE.

Since the early part of 1899, a vital change has taken place in the Irish Poor-law Medical Service—the service which has, heretofore, absorbed most of the Irish rising medical generation. By the Irish Local Government Act the administration of the system, the appointment and payment and allocation of duties of medical officers was transferred from the old Boards of Guardians, composed in due proportion of members elected by the local voters and members who acted *ex-officio* in virtue of property qualifications, to new boards composed wholly of the elected representatives. This change has placed the sole control of the service in the hands of the elected Guardians, who have, we regret to say, sought to place considerations of economy before everything. The Irish Medical Association, whose work it is to safeguard the interests and improve the condition of the Poor-law medical officer, considers it an imperative duty to point out to young practitioners the following facts:—(1) That the Poor-law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, the same or a less rate of payment given to less educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain.

We need go no further than to say that the Irish Poor-law Medical Service is a service to avoid. To all who contemplate entering it we emphatically say, Don't. So important is it that young medical men should recognise what life in the Poor-law Medical

Service means at present that we quote a short extract from a letter written by a member of it:—"We have no pay practically; no holidays. We are always on duty. We have no pension. We have no promotion. Consequently, every day spent in such a service is one day worse, which, I think, makes it fairly rank as the very worst service of any kind in the world, for any other service leads a man to promotion or pension. In addition, the fact of a man being in this service lowers his social status. Everything points to it being a service to be shunned."

Reforms must come finally, but they will only come, as they have come in other services, in consequence of the dearth of candidates. The various branches of the Irish Medical Association through the country have found it necessary to adopt the following resolution:—"That henceforth no medical man shall apply for or accept any dispensary appointment at a smaller remuneration than £200 per annum, or workhouse appointment under £120 per annum, unless both be held conjointly, when the minimum salary shall be £300 per annum." Already the effect of this is being felt, and many dispensary districts are vacant. We desire to point out to the young qualified man the importance of, in all cases, supporting the interests of the profession as a whole on this important question.

There are 159 workhouses and about 813 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service used to average about £114, but is rapidly coming down, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

*Qualifications.*—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age.

The appointment to both workhouse and dispensary lies with the guardians, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interests also possess great weight. In some districts an attempt has been made to insist upon the candidate being a member of the United Irish League. We need not—we trust—point out to any member of the medical profession that to endeavour to obtain a post on such a qualification as that of the membership of any political organisation is to commit an act which is unworthy of his profession.

*Duties.*—The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in many districts he has to make up all the medicines for the poor.

The pressure of these duties is in a great degree dependent on the goodwill of the guardians. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour in which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance. If, on the other hand, it is his misfortune to differ from the guardians, his position may become impossible. He may be peremptorily summoned in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay.

**Workhouse Hospitals.**—The number of unions in Ireland in 1899, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary surgeon. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

**THE IRISH LUNACY SERVICE.**

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries and emoluments averaging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the new Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant has been, heretofore, appointed by the Board of Governors, and will, in future, be appointed by the Committee of the County Council to which the management of the the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

**OTHER APPOINTMENTS.**

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are:—

- (1) Attendance on the Royal Irish Constabulary.
- (2) Attendance on the Coastguards.
- (3) Factory Surgeoncies.
- (4) Attendance upon the depôt soldiers who are not otherwise provided for.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

**The Coastguard Service.**—The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor-law Medical Officer. In this case, also, emoluments depend on the number of stations and men.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a

matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning.

*The names of the Professors, Lecturers, and Hospital Staffs of the foregoing Schools and Hospitals are not included in this place, being found in the advertisement of each Institution, as indicated below.*

**Scotland.**

NOTWITHSTANDING the increased competition which the recent vigorous growth of the great English provincial medical schools, added to the unsurpassed attractions of the historic Metropolitan hospitals, with their staffs of renowned teachers, ensures, the Scottish medical schools seem fully to retain their popularity, not only, as is natural, among Scotsmen and their colonial descendants, but among medical students from England, Wales, and Ireland, and, indeed, all parts of our Empire. In fact, if appearances be any guide, it would seem that the number of Oriental students attending classes in Edinburgh is increasing year by year. And undoubtedly the competition of other centres has had the advantage of making Scottish teachers bestir themselves, with the result that the efficiency of the medical schools is now much greater than a decade ago. The Carnegie bequest, which practically ensures free university education to all Scotsmen who are willing to take advantage of it, has considerably increased the number of undergraduates, but it is thought that the increase from this cause has now attained its maximum. The benefit of the second half of the bequest, *i.e.*, the improved equipment of the teaching schools and the encouragement of post-graduate research, are naturally slower in manifesting themselves, but will prove permanent factors in promoting the well-being of the Universities and Scottish education generally. Of the four universities, Edinburgh, of course, occupies the premier position as a medical school, but at Glasgow, Aberdeen, and St. Andrews, an almost equally good, indeed in individual details, better—training can be obtained. Two ordinary qualifications to practise are granted in Scotland—the M.B., Ch.B. of the Universities, and the triple qualification of the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. The standard of examination for the University degree is naturally a good deal higher than that for the triple qualification, and the curriculum wider. Nevertheless, the standard for the latter is being steadily raised, though, on account of the large number of examiners in most subjects it is probably slightly less uniform than that of the universities, where the examinations are conducted by the professors with one or more extra-mural assessors in each subject. Two features of the Scottish system deserve mention—first, as regards the co-ordination of various separate teaching bodies in each centre; second, as regards the conditions under which the students live...

Around each university there has grown up an extra-mural medical school, in which the teachers are hospital physicians, surgeons, and specialists unconnected with the university, but whose classes qualify for graduation. Thus the student has usually ample choice, and can, within certain limits, attend the teacher from whom he thinks he will derive most benefit, while the extra-mural lecturers, being unendowed and constantly recruited by fresh blood, have a permanent incentive to keep their courses up to the mark, since any slackness is at once followed by a diminution in the number of students' fees. In hospital work it is the same, the student having the option of attending a clinical professor and an ordinary physician or surgeon. A very important part of the student's clinical work, too, is done at institutions and under teachers quite unconnected with the universities; this is his dispensary practice, which may be taken at one of several dispensaries situated in the poorer districts of the towns. Until recently, practical training in obstetrics was one of the least satisfactory parts of the teaching in Edinburgh, and many students were in the habit of going to Glasgow to take their maternity work there, where the department is excellently organised and the material ample. Recently, however, steps have been taken which should render this unnecessary, and ought to give Edinburgh students quite sufficient opportunity of acquiring as good a practical acquaintance with this most important subject as they have, and previously had, of obtaining a theoretical knowledge of it. From what has been said it will be seen that university undergraduates and triple qualification men rub shoulders at every turn—in the wards, dispensary, and lecture-room. University students have the privilege of studying under both intra- and extra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, therefore, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versa*, and this can usually be done without much added expense or taking out many fresh classes, provided the change is not made too late in the curriculum.

For the rest, the student lives as he likes and where he likes; the authorities only demand that he shall attend classes with due regularity and diligence, and exhibit sufficient proficiency to pass his examinations. Most men live in lodgings, a few board with private families, and some live in the various halls of residence which have been established. In these last, too, the student is his own master, the halls being managed solely by a committee of the residents for the time being. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the Licence are £120, for the M.B. degree about £145; but almost every student finds it practically necessary to attend additional classes. On the whole, the cost of living is highest in Edinburgh, lowest in Aberdeen; in the former, while the rent of lodgings is lower than in London, maintenance, including clothing and provisions, is somewhat more expensive. Incidental expenses, amusements, &c., are, however, considerably less in the Northern capital. In Aberdeen, money goes much further than in the south, and the student ought to keep himself on about two-thirds of the funds required in Edinburgh.

#### THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of

the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Hanover Street, Edinburgh.

Scholarships, Fellowships, and Grants in aid of original research are now awarded annually by the Trust. For particulars, conditions, &c., apply to the Secretary.

#### UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, arithmetic and the elements of mathematics, and Greek, or French, or German.

The *annus medicus* of each year is held to be constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two courses of not less than fifty lectures each, exclusive of the clinical courses, in which lectures are given twice a week during prescribed periods. Two years of the five must be spent at the University, the remaining three years at any University of the United Kingdom, or other Universities or Medical Schools recognised by the University Court.

During the first four years the student must attend elementary botany, elementary zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than thirty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery; materia medica and therapeutics, medicine, and midwifery and the diseases of women and children during courses of not less than five months each. Eight of these subjects must be taken at a University or college affiliated to a University entitled to grant the degree of M.D. He must attend a course of twenty-five lectures on practical pharmacy in a University or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation he must have attended for at least three years a hospital which accommodates no fewer than 80 patients, and possesses a distinct staff of physicians and surgeons, and he must have acted as clerk in the medical and dresser in the surgical wards of such a hospital, and the practice of a dispensary, or of a physician and surgeon. He must also have had approved opportunities of studying (1) operative surgery, (2) mental diseases at a recognised asylum, (3) at a recognised hospital, post-mortems, fevers, and diseases of the eye, and (4) one of the following: Diseases of children, of the ear, nose and throat, or of the skin, (5) vaccination.

He must personally attend at least twelve cases of labour under the superintendence of a registered

medical practitioner, or six such cases, and, for at least three months, the practice of a midwifery hospital in which practical instruction is regularly given.

Every candidate must deliver on or before the date for lodging certificates for the final examination to the Dean of the Faculty of Medicine:

1. A declaration in his own handwriting that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master. (This declaration, along with a statement of studies, is appended to the schedule for the Final examination, and must be signed before the schedule is given in.)

2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates.

Each candidate is examined both in writing and *viva voce* :—

1. On zoology, botany, physics, and chemistry.
2. On anatomy, physiology, and materia medica and therapeutics.
3. On pathology.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

The examinations in anatomy, chemistry, physiology, botany, and zoology, materia medica and pathology are conducted, as far as possible, by demonstration of objects placed before the candidates.

Candidates who are ready to submit to an examination in the subjects comprised in the first division, *viz.*, botany, zoology, physics, and chemistry, may be admitted to examination in all or any two of these subjects at any examination held after they have attended a full course in each of the subjects professed.

Candidates who have passed their examination in the subjects in the first division may go up for examination in those of the second division at the end of their third winter session, but may postpone their examination in materia medica and therapeutics until the close of the summer session following.

Candidates who have passed the first and second divisions may be examined in the third division at the end of the fourth winter session.

Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division, when they have completed the fifth year of study.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for at least one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor of Surgery, which he may have made a subject of study after having received those degrees. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he may take, at option, gynaecology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., C.M. (old regulations), on the submission of a thesis approved by the Medical Faculty, provided that the candidate shall have passed the medical preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did

not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar, the candidate being examined in surgical anatomy, operations on the dead body, clinical surgery, and some of the special branches.

Candidates settled abroad, who cannot appear personally to receive the degree, may, after satisfying the Senatus to that effect, have the degree conferred on them *in absentia*.

*Fees* :—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas, and the proportion of this sum to be paid by a candidate at each division of the examination is registered from time to time in the University Court. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (old regulations, £5 5s.).

The total expenses of the curriculum, including examination and matriculation fee, is £146.

Bursaries and scholarships open for Session 1904-1905: Among the bursaries and scholarships open during the ensuing year are:—Freeland Barbour Fellowship of £100 in Anatomy, and Physiology, and Pathology. Allan Fellowship of £48 15s. in Clinical Medicine and Surgery. Heriot bursaries, applications to Treasurer, 20 York Place, before September 15th. Mackay Smith scholarship in Chemistry, value £25. Two Mackie bursaries for students in second and third years, whose pecuniary circumstances need assistance. Applications to Dean by October 1st. Four Buchanan bursaries. Two Sibbald bursaries of £30, and a medical scholarship of £40 a year for three years, particulars from Messrs. Mackenzie, Innes, and Logan, W.S., 23 Queen Street, Edinburgh, before September 15th. Two Thomson bursaries of £25 for four years, one conferred at each preliminary examination in October and March. Five Grierson bursaries (natives of Crawford and Leadhills have a preference). Names must be sent in before October 1st. Two John Aitken Carlyle bursaries of £28 for one year for proficiency in class examinations in anatomy and chemistry or physiology. Four Mackenzie bursaries of £20, in practical anatomy. Renton bursary of £20 for one year, for students attending classes of natural physiology, mathematics, chemistry, or political economy, who also can show they are in need of pecuniary aid. Two Crichton bursaries of £50, for four years, one competed for at each preliminary examination. Buchanan scholarship of £40 10s., for proficiency in midwifery and gynaecology, as shown by class work and in the final examination. Other scholarships are:—The James Scott, £42 10s. annually, in midwifery; the Ettles, £31 5s. annually to the most distinguished graduate; two Hope prizes, £30 annually in chemistry; two Crichton, £100 annually, for research in anatomy and physiology. One Vans Dunlop scholarship in preliminary subjects, value £100. Moutat scholarship in practice of physic, about £55. Houldsworth scholarship in Pharmacology, £40. For details of these, as well as a number of other prizes, bursaries, &c., the University Calendar must be consulted.

Graduation in Science: The University of Edinburgh also possesses a Faculty of Science which may confer two degrees, Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.). These degrees are given in pure science and in applied science. Candidates for the degree of B.Sc. in pure science must attend at least seven courses of instruction in the subjects selected by them during the course of not less than three academical years. Three of these courses must be on subjects prescribed for the first science examination, and four on those for the final examination. Four of these courses must be taken in the University of Edinburgh. The subjects for the first science examination are:—1, Mathematics or biology (first professional in medicine not accepted as equivalent to latter); 2, Natural philosophy; 3, Chemistry. For the second examination they may be selected from among the following: Mathematics, physics, astronomy, chemistry, anatomy, physiology, geology, zoology, and botany. Graduates

as B.Sc. may, after five years, proceed to the degree of D.Sc., undergoing an examination in the subjects chosen, and presenting a thesis founded on original work.

**Graduation in Public Health:** Similar degrees are conferred in Public Health. Candidates must be graduates in medicine of a University recognised by the University Court, and must matriculate for the year in which they proceed for examination. Before proceeding to the first examination they must produce evidence that (1) they have worked at least twenty hours a week during a period of not less than eight months, after taking their medical degree, in a recognised Public Health laboratory. Five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh, and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one, of at least three months' duration, on geology, such as the Senatus may approve of.

Candidates for the second examination of B.Sc. in Public Health are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two separate courses of Public Health, of at least forty lectures each, one dealing with medicine, the other with engineering, each in its relation to public health, in such manner as the Senatus shall determine. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' clinical instruction in a recognised fever hospital, and three months' instruction in mensuration and drawing.

Full details of the subjects included in the different courses are given in the official programme of the Faculty of Science, which may be obtained from the University (price 2d.).

In a similar manner to that described under degrees in pure science, a B.Sc. may after five years proceed to take the degree of D.Sc. in Public Health.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.; D.Sc., £10 10s.; total, £16 16s.

**University Hall, Edinburgh.**—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences akin to, though very much less pretentious than, the English University colleges. During the past six years several buildings have been acquired in Edinburgh for this purpose, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that several graduates now live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents. These are considered and voted on at a house meeting. In all disputed points Professor Geddes is the referee, while Dr. Ricardo Stephens is the rent treasurer, who will supply any further information required. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

**Medical School for Women.**—The medical teaching of women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical School of the Royal Colleges, and qualify both for the Edinburgh University degree and for the Licence of the Triple Board. The classes are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest,

#### UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No. 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary mathematics, and (4) Greek, French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and on passing, students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the assistant clerk, Matriculation Office.

The fees for M.B. and Ch.B. are £23 2s.; for M.D. £10 10s., and for Ch.M. £10 10s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s., for each winter session, and £2 2s. for each summer session of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospital, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within the last few years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, to cost, with equipment, upwards of £60,000, are now in course of erection for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £900 are appropriated to medical students, including an Arthur bursary for women, £25 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

**Queen Margaret College for Women.**—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded six years ago. Fees for the classes

at Queen Margaret College may be paid by the Carnegie Trustees.

#### UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery, besides a Lectureship in Tropical Medicine. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £130. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

**BURSARIES.**—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,183, may be held by students of medicine. (See "University Calendar.")

**THE DEGREE OF M.D.**—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary the Medical Faculty.

**Aberdeen Royal Infirmary.**—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

#### ST. ANDREWS UNIVERSITY.

##### UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE.

This University (session opens October 7th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in

medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

*University College, Dundee*, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken in the College. The United College, St. Andrews, offers classes for the first two years of professional study.

#### BURSARIES AND SCHOLARSHIPS.

**United College, St. Andrews.**—Malcolm bursary £25 a year, tenable for five years). Fourteen T aylour Thomson bursaries, £30 to £20, five tenable for one year, nine for two, open to women only proceeding to graduate in medicine.

**University College, Dundee.**—Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine, tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust bursaries of £25, tenable for three years. Applicants must have attended a public or State-aided school in Dundee for at least one year before examination. Bute bursary, annual income from £1,000 (men only).

**Preliminary Examinations.**—The dates of the next two examinations are September 23rd, 1904, and March 24th, 1905. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 10th, 1904, or March 8th, 1905.

**Fees for Degrees.**—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, *i.e.*, 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

**Class Fees.**—The fee payable in each of the following classes is 4 guineas, *vis.*:—Chemistry, Physics, Zoology, Botany, Physiology, Anatomy, Materia Medica, Pathology, Forensic Medicine, and Public Health, Medicine, Surgery, and Midwifery. The fee for the practical classes in these subjects is 3 guineas each. In Clinical Surgery, Clinical Medicine, Ophthalmology, Diseases of the Throat, Nose, and Ear, and Mental Diseases, the class fees are 2 guineas each. The fee for Public Health Chemistry required for the D.P.H., is £7 7s. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

**Dundee Royal Asylum.**—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.

Further information will be found in the Calendar of the University, published by Messrs. Blackwood and Sons, Edinburgh, or can be had of the Dean of the Medical Faculty, Professor Weymouth Reid, F.R.S.

**Dundee Royal Infirmary.**—The Infirmary contains 300 beds, with a special ward for the treatment of children. Three resident qualified assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Ticket for the Infirmary, £2 2s. each session, or £3 3s. a year. Further information on application to the Medical Superintendent.

#### THE COLLEGES.

The Royal College of Physicians of Edinburgh, the

Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations, the student may obtain the diploma of the co-operating bodies.

The holders thereof are enabled to register three diplomas under the Medical Acts, *viz.*, Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow. The diplomas are also recognised by the Army, Navy, and other public bodies.

The three co-operating bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery, as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following separate and distinct course of lectures, the certificate distinguishing the sessions and the schools in which the courses were severally attended. Anatomy, one course, six months. Practical anatomy, twelve months. Chemistry, one course, six months. Practical or analytical chemistry, one course, three months. *Materia medica*, one course, three months. Physiology, one course, six months. Practice of medicine, one course, six months. Clinical medicine, nine months. Principles and practice of surgery, one course, six months. Clinical surgery, nine months. Midwifery and diseases of women and children, one course, three months. Medical jurisprudence, one course, three months. Pathological anatomy, one course, three months. The candidates must also produce the following certificates:—(a) Of having attended not less than six cases of labour under the superintendence of the practitioner who signs the certificates, who must be a registered medical practitioner. (b) Of having attended for three months' instruction in practical pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicine to his patients, or a teacher to a class of practical pharmacy. (c) Of having attended for twenty-four months the medical and surgical practice of a public general hospital, containing on an average at least eighty patients, and possessing distinct staffs of physicians and of surgeons. (d) Of having attended, for six months, the practice of a public dispensary specially recognised by any of the co-operating bodies; of having been engaged for six months as visit-assistant to a registered medical practitioner. (e) Of having been instructed in vaccination.

*First Examination, Fee £5.*—The first examination shall embrace chemistry, comprising the following particulars:—Chemical physics, heat, light, and electricity; the principal non-metallic and metallic elements, and their more common combinations, also the leading alcohols, organic acids, ethers, carbohydrates, and alkaloids; the candidates will also be examined practically in testing; physics and elementary biology. The first examination shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must apply to the Inspector of Certificates on or before the Friday preceding the day of examination, and must produce certificates of attendance on one course of chemistry, one course of practical chemistry, one course of anatomy, and six months' practical anatomy.

*Second Examination, Fee £5.*—The second examination shall embrace anatomy and physiology, and shall not take place before the termination of the summer session of the second year of study. Candidates must produce to the Inspector certificates of attendance on the prescribed courses of anatomy, practical anatomy, and physiology.

*Third Examination, Fee £5.*—Comprises the subjects of pathology, *materia medica*, and pharmacology and advanced anatomy.

*Final Examination, Fee £15.*—The Final examination shall embrace the principles and practice of medicine (including therapeutics and medical anatomy, clinical medicine); the principles and practice of surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynaecology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English language, including grammar and composition; (2) Latin, including grammar, translation from specific authors, and translation of easy passage not taken from such authors; (3) elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, including the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following optional subjects:—(a) Greek; (b) French; (c) German; (d) Italian; (e) any other modern language; (f) logic; (g) botany; (h) zoology; (i) elementary chemistry.

Qualification in Public Health: The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 ros.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48 George Square, Edinburgh; and for those of the Royal College of Physicians, to Dr. R. W. Philip, 45 Charlotte Square, Edinburgh.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years previously, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination (1) On the principles and practice of medicine, including therapeutics; (2) on one of the following subjects to be selected by the candidate, *in which a high standard of proficiency is expected*:—(a) one or more departments of medicine specially professed; (b) psychological medicine; (c) pathology; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology. The examination is of a searching character extending over three days, the first of which is devoted to the examination of patients, *visu voce* and practical examination on methods of diagnosis—*e.g.*, microscopy of blood, clinical bacteriology, quantitative analysis, &c., and written commentary on a case examined. The second day is taken up by written papers, and the third by practical examination on special subject and orals.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, *materia medica*, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great

Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (a) Surgery; special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynaecological medicine and surgery; (e) medical jurisprudence and hygiene; (f) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship.

**LICENCE.**—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

**WOOD BURSARY.**—The examination for the Wood Bursary, of £60 per annum, tenable for three years, will take place on October 21st and 22nd, at the college. The subjects will be found in our advertising columns.

**DENTAL DIPLOMA.**—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

**Edinburgh Royal Infirmary.**—Clinical instruction is afforded at this institution, which contains 780 beds in the building, and 10 beds in a convalescent home under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the eye, ear, throat and teeth, and anaesthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follows:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.
2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.
3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.
4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

### SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is about sixty, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 1st.

### GLASGOW EXTRA-MURAL SCHOOL.

**St. Mungo's College and Glasgow Royal Infirmary.**—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. The college has been recently equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has over 600 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, erysipelas, burns, and diseases of the throat. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases—about 78,000 per annum—which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

**Appointments.**—All appointments are open. There are five physicians' and eight surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

**Fees.**—The fees for Lectures, including Hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to £67.

**Anderson's College Medical School, Glasgow.**—New and excellently equipped buildings were opened in October, 1887, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery. There are also provided a library and reading room, and students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from W. S. McCormick, Esq., LL.D., Carnegie Trust Offices, Edinburgh.

**Class Fees.**—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, and mental diseases excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.; afterwards free. For the following practical classes, viz.: Chemistry, botany, zoology, physiology, pharmacy, first session, £2 2s.; second session, £2 2s. Operative surgery, £2 2s.; laboratory fee, 10s. 6d. Public health laboratory, £11 11s.; with lecture, £12 12s.

**Anatomy Class Fees.**—Winter: First session (including practical anatomy), £4 4s.; second session (including practical anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of practical anatomy, the fee will be £1 1s. Summer: Lectures and practical anatomy, £2 12s. 6d.

**Western Infirmary.**—Fees: Hospital attendance, £10 10s. (permanent); clinical instruction, winter £3 3s., summer £2 2s., pathology, £4 4s. (systematic), practical pathology, £3 3s.; vaccination, £1 1s.

**Royal Infirmary.**—Fees: Hospital practice and clinical instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £4 4s.; vaccination fee £1 1s.

**Dental Curriculum.**—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 5 St. Vincent Street, Glasgow.

#### POST-GRADUATE COURSES IN SCOTLAND.

In Edinburgh a number of post-graduate courses continue more or less throughout the year.

In Glasgow, special courses in ear diseases are held in November and May at Anderson's College, and Post-graduate courses in pathology and bacteriology at the University in autumn.

[END OF THE EDUCATIONAL NUMBER.]

A HANDSOME presentation was last week made to Dr. Arthur Pugh, assistant to Dr. O'Kelly, on the occasion of his leaving Chipping Norton.

THE Carlisle Board of Guardians have decided to retain a bed for a year in the new sanatorium for consumptives at Threlkeld, at an annual cost of £78, for the use of Carlisle Union cases.

## Notes on Current Topics.

### The Value of Examinations.

EVERY cloud has its silver lining, and it may somewhat soften the student's inevitable aversion to examinations to know that Sir Thomas Barlow considers them invaluable training for after life. In a speech delivered at the distribution of prizes at St. Thomas's Hospital in the summer, he pointed out that the practitioner's life was made up to a great extent of examinations, principally *vidu voce* ones. Patients, and especially patients' friends, fill up half the doctor's visit by questioning and cross-questioning, and ready replies which can be substantiated by facts and illustrated by examples constitute the practitioner's greatest asset. The art of the student under examination consists in persuading the examiner that he knows what he is talking about, even if his real information is comparatively slender. The general practitioner who can do the same to his patients is marked out for success, and generally achieves it. The *vidu voce* examination provides excellent training in the art of smartly answering questions that come somewhat unexpectedly, and Sir Thomas Barlow thinks that they also help to banish one of the greatest hindrances to the young doctor, namely, self-consciousness. It is a comfort to think that the gentlemen on the other side of the table who smile superciliously on the stammering candidate are really his dearest friends, and that the incredulity that sometimes characterises their glance at the victim, far from being intended to pain him, is merely a method of encouragement in disguise.

### Medical Thinking and Medical Thought.

THERE is a great tendency in this busy age to reduce all the processes of life to a severity of form of the Gradgrind order. Everything is stripped of its trappings, and the essential alone is preserved. Newspapers give their news in brief paragraphs; the shorthand writer is replacing the confidential secretary; drugs are compressed into "tabloid" form. The same influence is apparent in what is usually termed the practical side of medical education. The student must be taught this, that, or the other, because he may need it; such and such a subject must be dropped out of his curriculum as it has ceased to be useful. A certain amount of well-considered change is inevitable if useful progress is to be made, but there is a great danger in the coaching and cramming that students have to undergo to meet the demands of the modern examiner that he will seldom come into touch with medical thought—at any rate, in its best and highest exercise. It is no disparagement to the up-to-date physician to say that he has not the time to devote to thinking that his old-fashioned predecessor enjoyed, and that what he gains in scientific method is, to a certain extent, acquired at the expense of scientific thought. The work-a-day man has to have another man to do his thinking for him, and to furnish him with the results. At least, so one is often led to suppose.

when instituting comparison between this age and former ones. There can be no doubt, however, that much, if not all, of the real pleasure of medical work is sacrificed by those who fail to enter into the spirit of medicine when they assume its practice. The student who wishes his life's work to be an intellectual pleasure under all conditions should take the earliest opportunity of placing himself on familiar terms with what we may call the mind of medicine. He cannot accomplish this better than by the study of the works of some of the old masters in medicine, who are still models on which all sound practice may be fashioned. Every student should buy such a book as "Graves's Clinical Lectures," or Sir Thomas Watson's "Principles and Practice of Physic," the first day he enters the hospital, and read it through once a year. By the time he is qualified he will have no difficulty in judging which is the best book on his shelves, and which gave him the greatest insight into medical thought.

#### The Voice of Authority in Medical Studies.

To a young man fresh from school the greatest danger of the early years of medical study lies in his disposition to take the word of his teachers for law. The tradition of all scholastic establishments is to magnify the pedagogue and to keep the pupil under, so that the latter comes to regard the opinion of his instructor as the last word to be said on each particular subject. So, too, with his books. The authors of the commentaries and treatises on which he is nurtured are mystic abstractions who knew all about the matters of which they write. If the student is ever to become a scientific man in the true sense of the word, he must, from the start, cultivate a respectful disrespect for everybody's word about the phenomena he observes, and never accept any statement that he is not able either to verify himself, or to find cogent evidence in favour of. Every fact in chemistry, anatomy, physiology, and medicine is capable of verification by observation or experiment, and in so far as in him lies the student should not let one pass without endeavouring to satisfy himself that it rests on a solid foundation. Dogmatism has no place in medical study. The student may have a high regard for the opinion of his teacher, but he should never be satisfied till he has followed all the steps through which that teacher's mind passed before arriving at the final conclusion. A schoolmaster may be very impressive in enunciating a law in mathematics, knowing that his position is unassailable—the law is an old one that has been demonstrated over and over again; but the scientific teacher is at the mercy of his pupils if he is "cock-sure" about anything without having proved it for himself. The darkest period of medicine was from the day of Galen to the day of Harvey; the period when all medical knowledge was centred in the works of the great writers, and every case was treated by the application of the methods recommended in those works. No name, however great and justly honoured, should be allowed to be a guarantee for a single fact that the medical man can find out for himself; authority has a very back seat in the domain of medicine. The student's training is not derived from reading books, but from finding out if what his books say is true.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I only have to refer "A Country Practitioner" to my original address for the following, which contains a sufficient answer to all his questions:—

"My own opinion is that while occasional abstinence (or continence) in married life is perfectly allowable and may have, as I have suggested, a high moral hereditary value, no artificial prevention is advisable save that which is produced by operation, when deformity or grave disease imperatively demands it."—Page 23 of published address.

I have no reason to alter or qualify this in any way.

I am, Sir, yours truly,

JOHN W. TAYLOR.

22 Newhall Street, Birmingham.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems to me that the national importance of this question more than justifies the prominence you have lately accorded to it in your columns. This intricate problem cannot be solved off-hand by the *ipse dixit* of any individual, no matter how distinguished he may be in other branches of scientific work. Nor will the matter be advanced by the triumphant detection on one side or the other of minor errors in the arguments of the protagonists of the discussion. The question was most ably raised by Dr. Taylor, and his views have been clearly if somewhat forcibly criticised in the article subsequently contributed by Dr. David Walsh to your columns. There can obviously be only one solution. Dr. Taylor is either right or wrong in his views that the fall in the birth-rate is due mainly to preventive practices among married folk, and that such practices are productive of the greatest moral and physical harm. If he is right he should be able to meet all criticisms that are brought forward in a clear and logical way. He has laid down the law in tones of such strong conviction that he owes it to his reputation to sustain his propositions with ample and adequate proof. Meanwhile, I trust the matter will be thoroughly threshed out in THE MEDICAL PRESS AND CIRCULAR, the only medical journal which has had the courage to bring this most important social problem to the front.

I am, Sir, yours truly,

DUNS SCOTUS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The original paper of Dr. Taylor was widely quoted and commented on in all our church journals, and I certainly gathered from their perusal that he said the diminishing birth-rate was due to certain restrictions practised among married people. These practices he condemned utterly and said that they wrought incalculable harm both upon parents and children that were born in spite of them. His main text was that married folk ought to have as many children as possible, and that claim he advanced without any reference to the means or social position of the parents or to the upbringing and the future of their offspring. I then wrote stating my position as a poor curate's wife, who has had to keep house and bring up three children on an annual income of £250. I asked Dr. Taylor if he thought I ought to have brought an unrestricted number of children into the world "on the strength of social and intellectual qualifications that fail to furnish the decencies of life reasonably demanded by my husband's station in society." I am much disappointed at Dr. Taylor's reply, which is to the effect that he has not enough data to say whether I ought to have married or not. That is not the point. I am married, rightly or wrongly, and I want to know how his rules apply to my case.

I am, Sir, yours truly,

A POOR CURATE'S WIFE.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

### NOTICE TO HOSPITAL AND COLLEGE DEANS.

The Editor desires to thank those gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

### NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

### GRATUITOUS COPIES.

A VERY large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

LETTERS from our Paris, Berlin and Vienna correspondents, and several communications from others, are unavoidably held over this week on account of the space devoted to educational matters.

### EPSOM COLLEGE—ELECTION TO FEMALE SCHOLARSHIP.

AN election to a Female Scholarship at this College will shortly take place, notice of which will be found in another column of this issue. Candidates must be between the ages of 7 and 13, and must be necessitous orphan daughters of duly qualified medical men who have been for not less than five years in independent practice in England or Wales. Form of application can be obtained at the office of the College, 37 Boho Square, W.

DR. Y. J. S.—You need not have any hesitation in using anti-phlogistine under the circumstances you mention. We believe it is an excellent preparation and should be glad to hear of the result in this particular case.

### POISONING BY OLEANDER, OR ROSE-BAY.

THIS beautiful flowering shrub which is such a prominent feature in the gardens of southern Europe possesses well-marked toxic properties and these are often turned to account by soldiers desirous of obtaining a furlough. A handful of leaves are infused in boiling water and the solution swallowed. In a case recently observed by Dr. Bonnette, in south Oran, the symptoms commenced with nausea, vertigo, prostration and a fall of temperature to 97° F.; the extremities became cold, with dilatation of the pupils, loss of pupillary reflex and anesthesia of the cornea. The heart became irregular and the pulse slow and thready with gasping breathing, constipation, and mental confusion merging into coma. These symptoms lasted throughout one day and recovery set in with green diarrhoea and a copious excretion of dark urine. The heart remained slow for some time after.

### A LEGAL VIEW OF MEDICAL PRACTICE.

The following anecdote was overheard recently at the Medico-Legal Society's Rooms.

The following is told of the late Lord Morris, when examining a veterinary surgeon at Coleraine.

"Now tell me this. The 13 grains—wouldn't they teetotally kill the devil himself if he swallowed them?"

The witness was annoyed and pompously replied:

"I don't know, my lord. I never had him for a patient."

From the bench came the answer:

"That's true, no, docter, sure and ye never had. More's the pity. The old bhoy's still alive."

### THE DIMINISHING BIRTH-RATE.

A CORRESPONDENT asks if the Birth-rate is diminishing throughout the United Kingdom, or only in certain localities. We have looked into the latest returns of the Registrar General to hand which include the eighty largest towns of England, Ireland and Scotland, and find the increase is pretty general but more marked in the largest cities. In Greater London with its vast suburban population the births during the last week were 651 below those of the corresponding period for the last ten years. As an offset to this, the deaths were 152 below the average.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 14th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. H. I. Barnard, Clinique. (Surgical.)

THURSDAY, SEPTEMBER 15th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchison: Clinique. (Surgical.)

FRIDAY, SEPTEMBER 16th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. L. Paton: Clinique. (Eye.)

## Vacancies.

**Birkenhead Borough Hospital.**—Junior Resident House Surgeon Salary £80 per annum. Applications to the Honorary Secretary, Birmingham General Dispensary.—Resident Surgeon. Salary £75 per annum, with furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

**French Hospital and Dispensary, 173 Shaftesbury Avenue, W.C.**—Resident Medical Officer. Salary £80 per annum with full board. Applications to the Secre ary.

**Halifax Union Poor-law Hospital.**—Resident Medical Officer. Salary £120 per annum, with apartments, rations, and washing. Applications to Arthur T. Longbottom, 4 Carlton Street, Halifax.

**Hereford County and City Asylum.**—Assistant Medical Officer. Salary £150 per annum, with furnished apartment, board, and laundry. Applications to the Medical superintendent.

**Horton Infirmary, Banbury.**—House Surgeon. Salary £80 per annum, with board and residence in the Infirmary. Applications to the Honorary Secretary, 31 Marlborough Road, Banbury.

**North Cambridge Hospital, Wisbech.**—Resident Medical Officer. Salary £100 per annum, with furnished rooms, attendance, coal gas, and washing. Applications to William F. Bray, Secretary.

**Royal Berkshire Hospital.**—House Physician. Salary £80 per annum, with board, lodging, and washing. Applications to the Secretary.

**St. Mary's Hospital, Paddington, W.**—Medical Officer in charge of "X" Ray Department.—Salary £150 per annum. Applications to Thomas Ryan, Secretary.

## Appointments.

**BAMFYLDE DANIELL, G. W., M.B.C.S.Eng., L.R.C.P.Lond.**, Anaesthetist to the Edinburgh Dental Hospital.

**BULLIPE, ARTHUR, L.R.C.P., L.R.C.S.Eng., L.F.P.S.Glasg.**, Medical Officer for the Hearts of Oak Friendly Society at Midmore Norton (Somerset).

**GRAHAM, JOHN, B.Sc., M.B., Ch.B.Glasg.**, Resident Assistant in the Victoria Infirmary, Glasgow.

**HOOLE, JOHN, M.B.C.S.Eng., L.S.A.**, Medical Officer of Health to the Ashbourne Rural District.

**LEWIS, S. WOLSELEY, M.D., F.R.C.S.**, Medical Superintendent of the Kent County Lunatic Asylum, Barming Heath, near Maidstone.

**McLAREN, GEORGE H., M.B.C.S.Eng.**, House Surgeon to the Birmingham and Midland Eye Hospital.

**NAPIER, A. HARPER, M.B., Ch.B.Glasg.**, Resident Assistant in the Victoria Infirmary, Glasgow.

**POLLOCK, ANDREW M., M.B., Ch.B.Glasg.**, Resident Assistant in the Victoria Infirmary, Glasgow.

**SHARPE, EDWARD S., M.B., Ch.B.Édin.**, Junior Assistant House Surgeon to the Stockport Infirmary.

**STANFUS, H. S., M.B.Édin., M.B.C.S.Eng., L.R.C.P.Lond.**, Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

**THOMSON, J. WHITE, M.B., Ch.B.Glasg.**, a Resident Assistant in the Victoria Infirmary, Glasgow.

## Marriages.

**HUMBY—BETH.**—On September 10th, at Nicol Road Presbyterian Church, Hatfield, Daniel Morgan Humby, L.D.S., M.B.C.A., L.R.C.P., to Edith Muriel, eldest daughter of A. T. Betts, Esq., of Hatfield.

**KENNEDY—BABINGTON.**—On September 7th, at St. Paul's Church, Gleneagary, William Player Kennedy, M.D., Gay Street, Bath, second son of A. D. Kennedy, Esq., Glen-na-geragh Hall, Kingstoven, to Alice Frances L'Estrange (Allie), youngest daughter of the late William W. Babington, Esq., B.A., of Cork, and Mrs. Babington, of Dunluce, Gleneagary, co. Dublin.

**KIRBY—TURLE.**—On September 8th, at St. John's Church, Whetstone, N. Laurence, second son of the late Frederick Baker Kirby, and of Mrs. Kirby, of Torrington Park, North Finchley, to Elizabeth Margaret, third daughter of James Turle, M.D., of North Finchley.

## Deaths.

**CARVER.**—On September 7th, at Torquay, Edmund Carver, M.D., late of Cambridge, aged 80.

**CHALMERS.**—On September 11th, at Leighton, Southborough, Esq., widow of the late David Chalmers, M.D., of Everton, Liverpool aged 78.

**DICKINSON.**—On September 6th, at Trebrea Lodge, Tintagel, William Lee Dickinson, F.R.C.P., elder son of W. Howship Dickinson, F.R.C.P., of Trebrea Lodge, and 10 Stanhope Place, London, aged 40.

**DUDGEON.**—On September 8th, at 23 Carlton Hill, N.W., Robert Ellis Dudgeon, M.D., in his 85th year.

**RIORDAN.**—On September 9th, at Roseville, Ireland, Gertrude, dearly-loved wife of Lt.-Colonel J. Riordan, R.A.M.C., B.I.P.

### HOSPITAL ISOLATION OF SCARLET FEVER: THE DESIRABILITY OF AN INQUIRY INTO ITS EFFECT.

By MEREDITH YOUNG, M.D., D.P.H.,

Medical Officer of Health, County Borough of Stockport.

THE hospital isolation of scarlet fever has been practised for so long, and has become such a routine preventive medicine prescription, that it seems almost heresy to entertain the slightest doubt as to its effective value. At the same time the benefits of the procedure have been most seriously questioned by a number of men of standing in the Public Health Service, and the arguments and statistics adduced by them in support of their contention, though vigorously assailed, still stand in the main uncontroverted. To the perfectly open mind the supporters of hospital isolation have, up to the present, done little more than effect what the eulogistic Russian war-correspondent would term "a masterly retreat." There are doubtless many who, like the writer, would gladly welcome a verdict in favour of the isolation hospital, provided that it was the genuine outcome of an exhaustive and independent inquiry. But the present position is that of Mahomed's coffin—half-way between heaven and earth—and it is a most disconcerting and disappointing one.

In my own town of Stockport, with a population of 100,000, a sum of about £20,000 has been spent during the past sixteen years on the isolation of scarlet and typhoid fevers alone, and the former disease has monopolised quite three-quarters of the available hospital accommodation; roughly speaking, therefore, the hospital treatment of scarlet fever, the utility of which both to the community and to the individual is so seriously questioned, costs this town on an average £1,000 per annum, and appears likely to cost more.

Thousands upon thousands of pounds of public money continue to be expended upon this doubtfully useful measure. And there can be no question but that local authorities are frequently so handicapped financially by this expenditure on hospital isolation that other public measures of indubitable benefit are passed by.

The wholesale and indiscriminate removal to hospital of scarlet fever cases is a measure not without other drawbacks than those mentioned by Dr. Millard and his followers. For example, it tends to weaken the sense of individual responsibility and leads to the relaxation of those proper

precautionary measures which should be taken by every householder on the outbreak of infectious disease in his family; and particularly is this the case when everything is done for the affected household free of expense. The wretched and far-reaching apathy which such a measure inculcates could not be better illustrated than by the words of a mother who had three children ill of measles, and who remarked to the writer that "she wished it had been scarlet fever, because they took them to the hospital for that and there was no bother with them then."

Dr. Millard, as is well known, has made a careful and thorough inquiry, and has published an abundance of statistics to show that hospital isolation has failed to materially reduce the prevalence or fatality of scarlet fever. Dr. James Niven, who has probably conducted a more elaborate inquiry into the question than anyone else, is forced to the conclusion that whilst hospital isolation of scarlet fever has reduced its prevalence in Manchester, "the reduction was not so great as could be desired." (Annual Report, 1901.) Numerous other practised observers have recorded varying opinions and collected valuable statistics. Evidence on all the main points and many of the side issues is thus already to hand, and much more would be abundantly forthcoming if some authoritative and independent body would undertake to formulate the most useful lines of investigation, and subsequently collate and analyse the material. Scarlet fever has been isolated more than any other disease for about twenty years, and therefore there should be a mass of useful and interesting evidence available at comparatively short notice.

Clinical, pathological, and bacteriological investigation is still required to make the story complete; and if the investigation be conducted on proper lines discoveries of the utmost importance might be the result. The etiology of scarlet fever is still obscure; its *causa causans* yet remains hidden; its variations in type and epidemicity are explicable only by the flimsiest conjecture; the prevention of return cases, the transmission of otorrhœa and rhinorrhœa, the causation of post-scarlatinal nephritis, the persistence of infectivity and a host of other matters require elucidation. We have abundance of evidence as to the occurrence of complications in hospital-treated cases, but to what extent have we similar evidence in respect of the home-treated cases? What evidence, again, have we at present of the occurrence of "return" cases outside the patient's own household? To these and many other associated problems there can surely be

found an answer if a proper stimulus to research be only given.

The main, if not the sole, objection to an inquiry into this matter is that it may "shake public confidence." But has not the confidence of the medical profession and of thinking laymen already been shaken? And is not the best manner to restore that confidence to court the fullest investigation and to search out the truth, whatever it may be, rather than to plunge our heads ostrich-wise into a mass of unconvincing statistics and empty platitudes?

The matter is one of considerable urgency, for many local authorities are now hesitating as to the adoption of isolation hospital schemes, in the hope that those of the profession on whom they rely for advice in such matters will adequately defend their theories or forswear them.

Would it not be wisdom also to somewhat extend the scope of any inquiry which may be held, and to ascertain whether there are any disadvantages attendant on the hospital isolation of diphtheria and enteric fever?

Dr. E. D. Marriott has suggested (*Lancet*, vol. i, 1902, p.1078) that in the Boer War hospital "aggregation" played some part in the disastrous diffusion of enteric fever. If there be any truth in this, would it not be well to learn it at once?

It is by no means an easy matter to say by whom the inquiry could best be conducted, if it be undertaken at all. The body to which probably most of those interested looked for a lead (the Incorporated Society of Medical Officers of Health) has on more than one occasion given evidence of its desire to avoid responsibility—to put the thing at its mildest. Moreover, this body is composed of experts, and an inquiry by experts into their own principles and practices would savour of the Gilbertian. If one were given a choice, one would unhesitatingly pronounce in favour of a Royal Commission or a Select Committee, for in this way one would certainly secure what is required—that is, men accustomed to weigh evidence calmly, to find a common-sense way through mazy arguments, and to sift statistics, whilst it would be possible to secure on such a body the very necessary services of one or more experienced general medical practitioners. Moreover, the verdict of a Royal Commission would undoubtedly carry weight with both professional men and laymen.

In conclusion, if some body is appointed to investigate this vital question, is it impudent or impertinent to draw their attention to four most excellent rules drawn up for the guidance of statisticians by Quetelet?

"1. Never have preconceived ideas as to what your figures are to prove.

"2. Never reject a number that seems contrary to what you might expect, merely because it departs a good deal from the apparent average.

"3. Be careful to weigh and record *all* the possible causes of an event, and do not attribute to one what is really the result of the combination of several.

"4. Never compare data which have nothing in common."

THE examination of the rats found on board the steamer at Hamburg from West Africa, which were believed to have died of plague, shows that this suspicion was without foundation. The discharge of the cargo has, therefore, been continued.—*Reuter*.

## FAMILY CARE OF THE INSANE. (a)

(A VISIT PAID TO GARDELEGEN IN NOVEMBER, 1903.)

By DR. C. WICKEL,

Principal Medical Officer at the Provincial Asylum of Meseritz, Posen.

TRANSLATED, WITH THE AUTHOR'S PERMISSION,

By CONOLLY NORMAN, F.R.C.P.I. (b)

At the first International Congress for the Relief of the Insane, with a special view to their Nursing Care in Families, held at Antwerp on September 1st, 1902, Alt, in his paper, stated that his chief reason for establishing family care in Gardelegen was to demonstrate that even at home in Germany this mode of treatment can be naturalised without a preliminary education of the population extending over many years, and, further, to show that suitable patients would be happier living in a family than even in an institution like Uchtspringe, where freedom of treatment is carried to the highest conceivable point.

At the present time, after family care has existed for five and a half years at Gardelegen, it can be said that the experiments made there, and the results obtained thereby, furnish a most full and complete proof of the justice of Alt's anticipations.

On an excursion which I took for the purpose of acquiring information in the autumn of 1903, it was my privilege to become familiar, from my own observations, with family care as carried out in Gardelegen, and I am happy to be able to report thereon in this place.

In the autumn of 1898, the first patients, namely, four women, were transported from Uchtspringe to suitable families in Gardelegen. In April, 1901, eleven female patients were sent. From that date forward, the number of cases in family care has increased rapidly and almost uninterruptedly, reaching the figure of 119 (chiefly female patients) in January, 1904.

The patients at Gardelegen are to be regarded as belonging to the institution of Uchtspringe. More than two patients are not committed to the care of any family at the same time. The number of families who act as hosts is constantly increasing. Only an exceedingly small number of such families have proved themselves unsuitable for the care and watching of patients. The return of patients to the institution necessarily takes place in some cases in which severe bodily illnesses or mental exacerbations occur.

In the year 1903, a head nurse was stationed at Gardelegen. The medical care of the settlement was at first managed solely from Uchtspringe. In the summer of 1903, a special physician was appointed who resides in Gardelegen, and takes charge of the patients in family care under the director (medical superintendent) of Uchtspringe, Dr. Alt. Dr. H. Stamm, who had familiarised himself at Gottingen, as physician to the asylum there, with the institution of family care, received this post.

Gardelegen, like the asylum at Uchtspringe, is situated on the Stendal-Hanover Railway, fourteen kilometres (between eight and nine miles) distant from Uchtspringe, or about twenty minutes' journey by train. It is a pretty, cheerful, little country village, the chief town of its district, having about 8,000 inhabitants. It has nice clean streets and solid well-built houses. On the whole, it gives a certain impression of prosperity.

Round the town and corresponding to the old fortifications and earthworks, run pleasure grounds and promenades. A handsome avenue leads out of the old town towards the new along which lie a few villas, but chiefly strongly built, decent, one-storey houses. A well-kept garden is attached to most of these houses. In this locality almost every house contains a patient.

(a) As this paper refers to one of the more recent German institutions for family care, which has attracted a good deal of attention abroad, I think this rendering of it may have some interest to the readers of THE MEDICAL PRESS AND CIRCULAR.—O.N.

(b) From Bresler's *Psychiatrich-Neurologische Wochenschrift*, June, 1904.

Gardelegen has no general water supply. The water comes from public pump wells. It is unobjectionable. The general sanitary condition of the town is very good. Infectious diseases seldom visit it, and typhoid especially has not appeared for a succession of years.

The number of houses open to receive patients is very considerable. Hereby is clearly seen how great an interest the population already take in the family care of the insane. I myself had several opportunities of confirming this by my own observation. A villager came to the house of the doctor while I was there and begged to be given a patient. He declared he would take all possible trouble, and that he had already prepared a room in accordance with regulations and under the advice of other hosts. Owing to the precautions which are adopted in the choice of applicants and to the great number of applications that had been already made, it was necessary at first to advise him to wait. Indeed, before a family receives a guest, the most exhaustive inquiries are prosecuted as to the calling and the character of the family, as to their employment, and particularly as to the conditions of their dwelling with special reference to hygiene. How completely this is done the paper of questions provided for this purpose, and which is appended hereto, will serve to indicate. In the dwelling of a family of hosts who had received patients for some time and were known as specially good at the work, people who even assisted the others with their advice, the wife of another host was waiting for the doctor and begged urgently that he might give her a patient once more. On the day before, in fact, her patient, who was a case of periodic mania, had been brought back to Uchtsprunge on account of a return of excitement. The woman was now afraid that perhaps she would be blamed for the re-appearance of excitement, and that in consequence no other patient could be entrusted to her again. She repeatedly represented that she would thus be disgraced "before the others." In company with the doctor, I visited the very great majority of the quarters where patients are maintained. Throughout, the dwellings were clean and well kept. The rooms set apart for the patients were faultless in their condition, roomy, clean, open to light and air, cheerful and provided with clean bedding. In case a room was not in absolute order, the family were always eager to excuse themselves and explain the reasons. Frequently more furniture was found in the patient's room than the regulations required. We saw some rooms which obviously were specially constructed or renovated for the reception of patients. These rooms were exhibited by the families with a certain pride.

When we visited a lodging, some member of the family immediately appeared holding a book which contains the rules about family care, which is also used for the memoranda of the doctor and of the head nurse as to the time of the visit, the medical prescriptions, the notes about clothing, renovation, improvement, &c. It also contains special columns to indicate the occurrence of the menses, the body-weight, and occasional convulsive seizures. Almost in every case the master or the mistress of the house was present. In Gardelegen, indeed, there is a great deal of home industry, particularly the preparation of mother-of-pearl. Therefore the inhabitants are not often absent from home. The hosts seemed good-natured, accommodating, and intelligent. Almost all of them reported without suggestion on the condition of their patient as to bodily state, occupation, and occasional alterations in mind. A master tailor communicated his observations about his patient, a child, *æt.* 8, in a very clear way such as would have been creditable to any trained attendant. The matter in question related to attacks of *petit mal*, appearing for the first time in an idiot boy.

The patients themselves came forward or were brought in from their work. They were, without exception, well cared for, clean in person and clothing, under and upper. Their condition of nutrition was very good. They all looked contented. Many of them seemed very happy. From the behaviour of the members of the family and from the attitude of the patients, it could

be concluded that their relation with each other was a friendly one. This was very noticeable when the patients were still children. In such cases, indeed, it frequently seemed that relations similar to those between parents and child existed.

In most cases the patients were employed in the kitchen peeling potatoes, washing, and the like, or they were helping the woman of the house in sewing. This, of course, was in accordance with the preponderance of female patients. Some of them accompanied the woman of the house on her journeys to the yard in care of fowl, &c. Others who were incapable of occupation sat in the common room with the members of the family. Some young patients were met on the street, watching the children of their hosts at play or taking part in their games. I asked a number of patients in the usual way whether they would not rather go back to Uchtsprunge, and whether Uchtsprunge was not a prettier and better place. In no case did I receive an affirmative answer. They all preferred remaining with the family of their hosts.

I will never forget with what joyful alacrity one worthy old lady, one of the eldest of the Gardelegen hosts, described the steps in the mental development of her patient whom she produced for inspection. In well-chosen language, she reported that the patient, when delivered over to her care some years before, could neither speak nor be induced to occupy herself, and even had sometimes to be watched closely with regard to cleanliness. Gradually the patient became more lively, began to occupy herself under constant instruction and verbal direction, learned, in the course of time, to sew and to darn, and is now a useful helper to her hostess in the house and at her work. The patient speaks little, but intelligibly. This was a case of idiocy, who is now *æt.* 19. Granted that in this patient perhaps a certain further development of the mental faculties might have taken place even in an institution, yet there can be no doubt that we must assign a great part of the striking and far-reaching result to the more genial influences of the family and to the exertions of the hostess and her belongings. According to the statement of the doctor, similar instances of the favourable influences exercised upon the mental condition of the patients in family care at Gardelegen have been repeatedly observed.

In a trusty and experienced family, a press for bandages and other dressings is kept. Any minor surgical dressing, &c., which is required is carried on there. Instruments and other surgical necessities for special cases are kept in the doctor's residence. Provision is made for bathing. A host's family has erected a little building in the yard attached to their holding, where there is a water supply and a tank with arrangements for warming water and two enamelled baths. In an ante-room to the bathroom a weighing machine is placed. Every four weeks at furthest each patient comes here in company with some member of the family and has a bath and is weighed. The host who built the bath-house and has to look after the machinery receives 30 pfennige (a little under 3d.) for each bathing, which is paid by the asylum. The baths and the weighing machine are also asylum property.

Eight of the guests belonged to the better classes, three ladies to the first and five to the second. Every two paying patients of the second class have a large and well-furnished parlour and a bedroom in common. Every lady of the first class has a sitting-room and a bedroom to herself. In a family whose house is situated in the street leading to the new town, two of these ladies live, old cases of chronic paranoia. They possess a prettily furnished bedroom and a large comfortable living room between them. The head nurse is provided with lodging in one of the better families. She takes her meals together with a lady of the first class.

Nearer the middle of the town, in the vicinity of the church square, a woman who was formerly an inspector of schools, and who lived alone, had a very good and nicely furnished dwelling of considerable size. Two ladies live with her who are also old-standing cases of chronic paranoia. The hostess devotes herself

entirely to her two patients. She cooks for them, looks after their apartments, and goes for walks with them.

In a shopkeeper's family a young imbecile lady was taken care of. She had two handsomely furnished and spacious apartments. She appeared quite contented, and announced that she was going in the evening with her host's family to the circus. The doctor told me that this patient could not get on at all at home, and was very troublesome in the institution, but had done remarkably well up to the present in family care.

It has never been observed that a patient was overworked, or made game of, or worried by the inhabitants of the town. Absolutely no untoward event worthy of mention has occurred up to the present in connection with family care in Gardelegen.

When patients of the third class (public patients) are admitted to the institution at Uchtspringe, their relations are required to signify beforehand that they agree to the transfer of the patient to family care, if such a course should be considered desirable having respect to the nature of the case. With regard to patients of the first and second class, relatives are asked in each particular case whether they consent to the patient being placed in family care. Since a special physician has been on the spot, this consent has always been gladly given. Furthermore, individual relatives of patients of the third class who at first had doubts about the placing of their people in family care became perfectly content with this method after they knew that there was a doctor in residence, and at their visits they expressed their complete satisfaction. In connection with this I may be allowed to make a brief observation upon some points which make it apparent how valuable the presence is of a medical man devoting himself entirely to family care and living on the spot. The doctor learns to know more thoroughly not only his patient but also the family of the host by the intimate and almost daily intercourse that he has with them, and he is thus in a better position to utilise the peculiar qualities of the people for family care. He is able to commit to them particular patients according to the foresight and cleverness shown in particular cases, and he can thus individualise better in the location of his patients; but, above all, the constant interest of the doctor in the patient calls forth from the host and his family a correspondingly heightened interest. By commendation of particularly excellent guardians, by reference to the example of others, and by the eventual removal of a patient who is hard to manage to a more able guardian, and the substitution of one that is easier to manage, emulation is kept alive among the hosts. Without doubt, a rivalry of this kind, a certain competition, an effort to do their best, at present exists among the families of the hosts in Gardelegen, and this is a very desirable thing in the interests of the patients. Very notable in this connection is the expression already referred to of the woman who feared she would be disgraced "before the others."

Alt has already shown in the most striking way how much always depends upon the cleverness and activity of the physician in the introduction and successful development of family care. It is scarcely necessary to particularly mention here that the choice of the patients who are to be committed to family care needs the most skilful consideration.

With reference to the forms of mental trouble in the persons committed to family care in Gardelegen, congenital and acquired conditions of weak-mindedness come first, and also old, quiet paranoiacs, forms of disease which are already recognised as being eminently suitable for family care. (α) The following table gives details:—

Forms of Disease.	Grown-up Patients of		Children of	
	Male Sex.	Female Sex.	Male Sex.	Female Sex.
Paranoia .. .. .	2	27	—	—
Imbecility, Milder Forms of Idiocy .. .. .	11	51	2	20
Epilepsy .. .. .	1	3	—	—
Periodic Insanity .. .. .	—	1	1	—
Total .. .. .	14	82	3	20

It is in contemplation to erect, in the course of time, a little central hospital in Gardelegen for the reception of patients who are temporarily excited, or who suffer from severe bodily illness. In the central hospital an examination room and a room for drugs and surgical necessities and bathing accommodation will be provided as well as a residence for a head attendant. Family care would thus be carried out around a small infirmary as at Jerichow, according to the plan designed by Alt, and called by him the German system of family care.

A visit to the family care settlement at Gardelegen presents a highly cheerful picture of earnest, active, successful progress. We here behold a practical experiment in family care on a large scale which has been crowned with success, such an experiment as is well designed to be an example, and to serve as an example. May it contribute to excite further that interest in family care of the insane which, up to the present, has been constantly increasing in Germany, and may it tend to smooth the way for the freest and most natural of all methods of relief for the unsound of mind.

The communications which the Medical Superintendent, Dr. Alt, made to me with reference to maintenance cost may be of interest. "The cost of clothing including boots and shoes, and including the renewal of articles worn out during the year, amounts to 77 pfennige per head daily. The amount spent on repairing shoes in the last year ran to 0.3 pf. The income of the physician stationed at Gardelegen, and of the head nurse set apart for looking after the patients, amount respectively to 10.6 and 4.4 pf. The latter charges will, of course, diminish proportionately with the increase and extension of the system. The cost of medicines has heretofore been at the lowest, amounting to about 0.25 pf. Tobacco is not given by the institution to patients in family care, who very often receive tobacco and cigars from their hosts as an encouragement to work, or reward for work accomplished. The total cost of a patient at Gardelegen by the day amounts to a certified expenditure of from 80 to 102.65 pf. The latter figure, is, therefore, about 17.35 pf. lower than the maintenance in the asylum for a grown-up patient (a third-class patient at Uchtspringe costing 1 mark 20 pf. per diem), and very much cheaper than the total cost of a patient in the asylum. According to last year's balance sheet, the total cost of a patient in the institution amounted to 172.19 pf. per diem.

"The family care of patients of the better classes, on the other hand, offers unmistakable advantages compared with asylum care, inasmuch as, for the paying patients at present in Gardelegen—three ladies of the first class and five of the second—7.75 marks daily less is paid out than is received."

Without further argument, these details show clearly that to the many other advantages which it brings with it we must, in deciding upon the question of the family treatment of the insane, add a considerable pecuniary profit which can by no means be put in the last place.

In conclusion, I must here again express my warmest thanks to the medical superintendent, Dr. Alt, for all the kind help he has given me, and also to Dr. Stamm, who showed me round.

#### APPENDIX.

List of Questions to be considered in allocating patients to family care:—

(α) The number of persons in family care in Gardelegen has risen from 119 to 142. Seeing that here are in addition 62 patients in the attendants' village at Uchtspringe and in the neighbouring villages, and that there are besides in Jerichow and its vicinity 146 patients located in families, it is to be observed that at the time of the writing of this paper the number of persons in family care in the province of Saxony has already attained to 360.

1. Full name of host? Address? Age? Religion? Married or Widowed? (age of wife or housekeeper). 2. Total number of members of household? (a) children? number, age, sex, employment; (b) lodgers, servants? 3. Employment or trade of the host? Is there constantly a member of the family at home? 4. Do the family live in orderly comfortable conditions? Do their means of subsistence come from their own industry? 5. What is the general impression which the family makes? 6. How does it stand with regard to orderliness and cleanliness (of dwelling, clothing)? 7. Does any suspicion exist of drink or tuberculosis? Have any cases of mental disease appeared among the family? 8. Why do the family wish to take charge of patients? How many do they want, and of which sex? Do they express any other special wishes regarding them? 9. How is the holding situated? (enclosed by other holdings or by dwellings in the neighbouring streets). 10. Of what does the holding consist? (offices, byres, arable). 11. How is the arable situated? the garden? 12. Do the family own cattle? (horses, goats, pigs, fowl). 13. Water supply? Where is the well situated? Is the water good and well flavoured? Where is the cesspool? 14. Privy? 15. House? (brickwork, timber, cellar, roof, architectural condition). 16. Dwelling of the family? (No. of rooms, ground plan, kitchen, &c.). 17. Where does the family spend the day? Living room, eating room (size, air, light, heating, aspect, floor, furniture). Are there beds in the living room? 18. Sleeping rooms of patients? (a) Air space (area of floor, height of room); (b) No. and size of windows, aspect, light; do the windows look out on the street or yard? have they movable sashes? (c) How do the doors lead? (d) Walls? (how covered, hangings, dryness); (e) articles of furniture? (f) Floor (covered? cellar underneath?) (g) Ceiling? (h) Heating? (i) Bed? 19. Are there any other dwellings under the same roof? If so, who occupies them? Occupier's trade, number of children, sex, age; servants, lodgers, other members of family; moral character. 20. Report, if such be forthcoming, from someone who can vouch for—(a) general respectability (character, repute, mode of bringing up children); (b) domestic circumstances of the family.

### Paris Clinical Lectures.

## THE MEDICAL TREATMENT OF CANCER OF THE STOMACH.

By PROFESSOR ALBERT ROBIN, M.D.,

Member of the Academy of Medicine; Professor Agrégé at the Faculty of Medicine of Paris; Physician to the Paris Hospitals.

I DREW your attention just now to a man, æt. 65, in the Serres ward, pointing out to you that his extreme emaciation and the straw-yellow hue of the skin were suggestive of the existence of a neoplasm. As a matter of fact, he is suffering from cancer of the pylorus. For a year past he has suffered from loss of appetite and progressive enfeeblement; he complains of pain in the region of the stomach associated with vomiting of glairy material mixed with food. I will take advantage of this case to discuss the symptomatology of gastric cancer, and more particularly its treatment.

The onset of carcinoma is, as a rule, insidious and gradual. The principal symptom is loss of appetite, with repulsion for particular articles of food, such as meat and wine. Nevertheless, one occasionally meets with cases in which the appetite is increased instead of diminished. Vomiting is one of the most constant symptoms of gastric carcinoma, and is due to the situation of the growth at the orifices, to disturbances of the

chemistry of digestion and the irritation caused by the presence of the growth itself. The most characteristic sickness is that which occurs on rising on an empty stomach, or during the day, preceded or accompanied by extreme nausea. The vomit consists of glairy mucus, which is brought up without effort, as it were by mere regurgitation, the so-called "cancer brash." In some cases the vomiting is purely alimentary, the food being returned some hours after meals, with great relief to the patient, whose stomach is thus emptied of its contents. These may be returned unaltered, but usually there is fermentation, and the vomit has an acrid or putrid odour. Under the microscope we see sarcinæ, numerous micro-organisms and, according to Boas, one long bacillus in particular, to which some authorities accord a special diagnostic value. There is an absence of hydrochloric acid, and there is only a minute quantity of peptone, while, on the other hand, fermentation acids are present in abundance. Acid fermentation is much more common in gastric carcinoma than gaseous fermentation. Lastly, we get the so-called "coffee-ground" vomit due to the presence of altered blood that has oozed from eroded vessels. This may be accompanied by melæna or not, and melæna, on the other hand, may exist without coffee-ground vomit. Copious hæmatemesis is exceptional in gastric carcinoma, and its occurrence points rather to gastric ulcer. Another cardinal symptom is pain. This is very common, but it is far from being as acute as in ulcer. Cancer patients do not suffer much from acute attacks of pain; they complain of a feeling of weight with occasional sharp pangs over the growth, which is tender to the touch. They are rarely free from this distressing sensation, even between meals; it is not at once increased by the ingestion of food, but gradually increases in intensity as digestion proceeds, with some pyrosis.

Severe pain on palpation of the tumour indicates the existence of partial perigastric peritonitis. Really severe pain, however, is rare and occurs only when the fibres of the pneumogastric are involved by the growth. Intestinal troubles are common, constipation being the rule, diarrhœa supervening only in the terminal stage.

The exact situation of the neoplasm may often be determined by palpation. In the case before us there is a prominent, diffuse hard tumour on the anterior surface. The stomach is not distended, and this shows that the pylorus is intact. To complete our investigation we must have an analysis of the stomach contents. Some years ago the absence of free hydrochloric acid was regarded as pathognomonic of cancer of the stomach, but this is not the case, since it may be wanting in many other affections, as, for instance, chronic gastritis, hyposthenic dyspepsia, &c. Moreover, in some cases of gastric carcinoma the acid is not only present, but is present in excess, and I have noted this in eleven out of 250 cases of the kind. Nevertheless, the point is one to be observed, because the absence of acid may confirm a suspicion based on other inconclusive facts. When present in excess the probability is that the cancer has supervened on an ulceration of long standing. Lactic acid is usually present, and in Germany its formation was at one time declared to be a distinctive sign. This, however, it is not, for it is absent in a quarter

of these cases, and, on the other hand, is met with in simple dyspepsia.

Leucocytosis seemed likely at one time to afford us valuable information in this connection, but experience has not confirmed this conclusion, in short, our diagnosis must be based on the clinical examination of the patient, not only of the stomach, but also of the other organs, in which there may be metastasis, or which may be secondarily involved by the gastric affection. The liver in particular must be carefully explored as well as the omentum, the peritoneum and the umbilicus. Look out also for enlarged glands above the left clavicle, which, if present, possess grave significance, in that they contraindicate surgical intervention. In the case before us there are no enlarged glands. Lastly, examine the lower limbs to see if there be oedema or possibly *phlegmasia alba dolens* of the veins of the calf. The examination of the urine affords no assistance.

Among other complications the most frequent, after those already mentioned, are affections of the broncho-pulmonary apparatus. Then, too, there may be a rise of temperature, brief, irregular or intermittent, attacks of fever, due to the absorption of the toxic products of gastric fermentation. Sometimes the temperature remains above normal, a form of septicæmia. We can do nothing to control the two last, but the first variety yields to the administration of antiseptics. Lastly, we may get various symptoms of intoxication—coma, tetany, polyneuritis, and so on—but these are altogether exceptional.

In view of the advances that have been accomplished in the surgery of the stomach, one is apt to suppose that the *rôle* of the physician herein has disappeared. Nothing of the kind. We may concede that medical treatment holds out no prospect of recovery, that it can at most attenuate the more distressing symptoms and mitigate the causes of the pain. Moreover, we meet with cases which are inoperable by reason of the extreme enfeeblement of the patient, and who, by appropriate medical means, may so far regain strength as to become able to withstand an operation.

I need hardly tell you that the curative treatment of cancer has yet to be discovered. Still it is useful that you should be told of the various remedies that have been tried because even if they do not cure, they are sometimes very useful palliatives and adjuvants. Condurango, for instance, used to be highly thought of, though in reality it is really a tonic bitter. It is still given as a tincture or fluid extract. Iodide of sodium, methylene blue, and bichromate of potash, in doses of from a fifth to one grain, conium, tincture of thuja, &c., &c., have all been tried, but I have never obtained any results worth speaking of. I have not experimented with various anti-cancer sera, but those who have done so do not appear to have much to say in their favour.

Some years ago Fiessinger and Jaboulay claimed to have obtained great benefit from muriate of quinine in the treatment of cancer in general. The treatment is applicable to the treatment of cancer of the stomach, and in my hands it has certainly appeared to delay the progress of the disease and to mitigate some of the symptoms. Later on I will compare the results of this treatment with those of surgical intervention.

Muriate of quinine is administered by the mouth,

by the rectum, or hypodermically. The average dose is 16 grains a day. It is best given by the mouth, but sooner or later the stomach becomes intolerant. *Per rectum* it ultimately excites tenesmus, and subcutaneously it is painful. Consequently, my plan has been to alternate the three modes. For eight days I give twice daily in the epigastric region an injection of, at first. ℞ ℞, then ℞ cxx of a solution of ʒvi of the salt in ʒxij of sterilised distilled water. During the next eight days I give 8 grains of the salt in cachet form, either fasting or a short time before food or milk, and a like quantity in suppository, just before bed-time. Then I return to the injections, and so on. If tolerance supervenes towards one method of administration we make up the dose by the mode that is still tolerated. In some patients we can give as much as 20 or even 30 grains daily, but this is exceptional.

Muriate of quinine seems to me to be one of the best palliatives, and under its influence I have often witnessed a remarkable improvement. I reinforce the action of this salt by associating it with two other products which appear to me to exert a favourable influence in retarding the evolution of the disease, *viz.*, arrhenal and bromide of gold. Arrhenal in 5 per cent. solution is given in 10-drop doses twice daily for five days. Then for another five days I give a tablespoonful of a solution containing one grain of bromide of gold in 10 ounces of water. Such is the fundamental treatment of carcinoma, a plan which, it is true, gives very modest results, but which will nevertheless bear comparison with those of surgical intervention as usually practised.

The next important point to consider is that of alimentation. There is a tendency when gastric cancer is diagnosed forthwith to place the patient on milk diet. This is often a mistake. There are cases in which milk diet is appropriate and others in which it is not. We may put on the strict milk diet patients with gastric intolerance or pyloric obstruction, those who have an insurmountable distaste for food, and lastly, those who suffer from hæmatemesis. The quantity must be adapted to the capacity of the particular patient, and every means must be employed to ensure its being tolerated.

In deciding the question of what food to give, you must be guided by the state of the intestines. If the intestinal functions are more or less disturbed they will be unable to make up for the inadequacy of gastric digestion, consequently we must discard meat, which excites repulsion, and insist on a vegetable diet, selecting substances rich in nitrogen in order to maintain as far as possible the intake of nitrogeous matter. If, on the other hand, the intestinal functions are in fairly good order we may order a mixed diet adapted to the state of the stomach. Under these conditions, by getting the patient to eat he can be kept going for a tolerably long time. To get him to eat, however, we must give him an appetite, and it is here that we must have recourse to bitters. Among the so-called "apératifs" or appetite-givers is the persulphate of soda. It must be given in weak solution, and stopped as soon as the appetite begins to return; in any case, discontinue it in eight days (persulphate of soda, gr. xxx, distilled water, fl. oz., x. A tablespoonful half an hour before lunch and dinner). Metavanate of soda is another good appetite-restorer.

(Metavanate of soda, gr.  $\frac{1}{2}$ ; distilled water, one pint; dose one tablespoonful.) Failing success, you can try a combination of the tinctures of gentian and quassia with jaborandi and nuxvomica. When you have induced the patient to eat you must assist the digestion, since we cannot trust to his unaided powers. You will, therefore, prescribe hydrochloric acid and digestive ferments—pepsine and malt during the meal and a keratinised pill of pancreatine after the meal.

Fermentation must be controlled by the administration of fluoride of ammonium (fluoride of ammonium, gr. v; distilled water, fl. oz., xij. A tablespoonful with lunch and dinner). When the fermentation causes pain and vomiting give a teaspoonful of the following mixture immediately after eating and another as soon as the pain begins: Subnitrate of bismuth, i drachm; carbolic acid, 15 drops; chloroform water, 4 fl. ounces. If the pain be very severe you may order occasionally a teaspoonful of the following: Cocaine muriate, i grain; codeine, i grain; lime water, 5 fl. ounces; chloroform water, 1½ ounce. In presence of intense pain apply a blister to the epigastrium, and powder the raw surfaces with powdered opium. If the pain be caused by acid fermentation giving rise to pyrosis, prescribe the following powder: Precipitated chalk and hydrated magnesia, aa i drachm; soda bicarb., 1½ drachm. Mix and divide into twelve powders, one to be taken as required.

Then for the vomiting, when persistent, put the patient on a strict milk diet, and before each drink of milk give him 4 or 5 drops of the following solution: Picrotoxine, i grain; rectified spirit, q.s. to dissolve; hydrochlorate of morphine, i grain; neutral sulphate of atropine, gr.  $\frac{1}{4}$ ; ergotin Bonjean, ℥ 16; cherry laurel water, ℥ 180. If nothing whatever can be tolerated, abandon the milk and nourish the patient by rectal enemata. This course is also advisable when there is hæmatemesis. Among other tonics I may mention subcutaneous injections of glycerophosphate of soda in 5-grain doses daily for a month.

Our patient is obviously in a very bad way. Nevertheless, since his admission a week ago he has gained some 25 ounces in weight. Of course, he cannot recover, but do you suppose that surgical intervention would give a better result? According to recent statistics pylorotomy or gastrectomy gives an operative mortality of about 26 per cent. The immediate results of the operation are indisputably admirable in such patients as survive the operation, the digestive functions improve, the pain subsides and they gain in weight. Unfortunately, the improvement is not of long duration, and if the lymphatics are involved, which is the rule, the growth recurs in other organs, and death supervenes from recurrence, cachexia or metastasis. Most of such patients under my own observation have succumbed to broncho-pulmonary complications. The average period of survival is one year, and by purely medical treatment the average period is eight months. Under these circumstances I really hardly care to expose the patient to an operation that kills three patients out of ten, on the off-chance of obtaining a prolongation of life for three months. You will bear in mind that the surgical is the best treatment when cancer can be diagnosed with certainty. In one case, under Doyen, the patient survived three years and a half,

and in that instance we were unable to agree upon the diagnosis quite at the onset. The tumour was removed in its entirety and life was prolonged beyond anything that medical treatment proper could offer. Such cases, however, are exceptional.

Our patient is too feeble to bear such an operation. One might perform gastro-enterostomy, but the operative risks are just as great and the operation would only relieve the pyloric stenosis. When successful this operation sometimes procures an improvement in the symptoms and an increase in weight, but the strength does not return, and the characteristic yellow colour of the skin persists. That is not surprising, since the operation has not removed the cancer, and has for object merely to prevent gastric stasis. The disease runs its course, and the patient is carried off by one or other of the complications. Such patients do not live longer than those who refuse operation.

To sum up, there is no curative treatment of carcinoma, but there is a palliative medical treatment which enables us to prolong life for considerable periods. In any event, if we do not markedly prolong life, we are in a position, with the means at our disposal, to assuage the patient's sufferings and to imbue him with a certain hopefulness. It is only in the painful cases, where the means I have described fail to afford any relief, that we are justified in having recourse to gastro-enterostomy, which, in my opinion, will always be in the nature of an exceptional operation.

## British Health Resorts.

### X.—FALMOUTH.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

AMONG Cornish health stations Falmouth very rightly occupies a foremost place. This picturesque old port, sheltered on the west side of its extensive and much indented harbour, has won the enthusiastic advocacy of such distinguished physicians as Sir Joseph Fayrer and Sir Edward Sieveking; and medical men in all parts of the country have testified to the benefits of this highly favoured resort on the Cornish Riviera.

The situation, conveniences, and climatic conditions are such as peculiarly fit the place for a winter residence. The abundant and semi-tropical vegetation affords clear evidence of the mildness and equability of the climate. Falmouth in the summer months is for many persons undoubtedly enervating; and even in late spring we have found it distinctly relaxing. But for the aged and the infirm, the delicate and the convalescent, and particularly for the subjects of chronic respiratory affections Falmouth can supply much that is of the greatest benefit. For those enfeebled by years or the attacks of disease this sheltered, old-fashioned marine residence provides protection from the stress of winter weather and allows of the maintenance of a fairly free open-air life throughout the year.

Falmouth possesses an important Meteorological Observatory, and its records extend from the year 1867. These returns clearly indicate the prevalence of climatic conditions particularly desirable for the physically feeble. Much sunshine is enjoyed, the temperature is equable, and the mean of the maximum and minimum temperatures is about 50°; the mean range being between 9° and 10°. The air possesses peculiarly balmy qualities, and there is good protection from winds. Sharp frosts are almost unknown, and such fogs as occur are generally free from irritant properties.

Endless interest circles about the spacious bay, the well-protected harbour, and the winding river Fal. The immediate district is rich in places of historic and natural interest. The town and vicinity offer much that is pleasing to artist and antiquary. Persons of all tastes will find in Falmouth congenial material for study.

The hotels, viewed from the standpoint of health-seeker and invalid, leave much to be desired, but good apartments are always available.

We have carefully studied the health resources of this resort, and consider it particularly adapted for the special requirements of those who, from the wear and tear of years or the encroachments of disease, require a peaceful, regulated, equable and protected life. For chronic invalids it can offer many attractions. It is, however, perhaps most useful as a winter residence for chronic bronchitis, sufferers from laryngeal affections and those who are the subjects of chronic tuberculous and other slowly progressive forms of pulmonary disease. Patients with chronic renal disease should do well in Falmouth; and some forms of nervous derangement may be expected to gain benefit from residence in this quiet town.

It is not for us here to describe the many attractive features which the enterprise of man has added to the benefits so richly provided by Nature: (a) it suffices to say that much has been accomplished to meet the requirements of the health-seeking visitor.

Falmouth is 306½ miles distant from London. The Great Western Railway run excellent trains in a little over seven and a half hours. (b)

PARIS, September 18th, 1904.

### TREATMENT OF ACUTE RHEUMATISM.

THE classical treatment of acute rheumatism has been for years salicylate of soda. It acts on this affection as a specific, like mercury on syphilis and quinine on intermittent fever.

In 1876, Stricker proclaimed the efficacy of salicylic acid, already tried by Buss, of St. Gall. But it was Germain Lée who, a year later, in a memorable communication to the Académie de Médecine, indicated the rules of the treatment of rheumatism by salicylate of soda.

Not only should the treatment be prescribed at the outset, but if the fever be high, large doses should be given—two drachms daily. For children, a drachm should not be exceeded. Salicylate of soda irritating the stomach, it is best given in Vichy water or in a mixture, as—

Salicylate of soda, ʒiij.

Rum, ʒj.

Syrup of orange water, āāʒiij.

From two to eight tablespoonsful a day.

The treatment should not be suspended with the cessation of the pain; to insure durable effects it should be continued in decreasing doses for fifteen days.

Salicylate of soda is toxic for some patients. The intolerance is shown by nausea, vomiting, vertigo, and sometimes by heart troubles, which may terminate in syncope.

The drug also provokes congestion of the kidneys; by accumulating in the economy it gives rise to grave

(a) See "Old Falmouth." By S. E. Gay. (London: Headley Bros.) The Corporation of Falmouth issue a useful guide. (London: The Health Resorts Association.) Messrs. Ward, Lock and Co. have published a useful guide which contains much data regarding meteorological conditions. A useful table respecting the climatic state of Falmouth appears in "The Climates and Baths of Great Britain." (London: Macmillan and Co.) Vol. I., p. 55.

(b) See "The Cornish Riviera." Published by G.W. Railway, Paddington, W.

toxic accidents when the function of the renal organs is compromised. Thus, when a patient suffers from chronic nephritis, salicylate of soda should not be prescribed. The same may be said of those suffering from arterio-sclerosis, from heart disease, and in pregnant women by reason of its abortive properties.

In all these cases, other drugs may be prescribed with more or less benefit.

It is thus that *antipyrim*, recommended by Masius Bernheim, can be substituted. It is prescribed in daily doses of forty-five to sixty grains. It relieves the pain and lowers the temperature, but it has not the specific action of salicylate of soda.

*Salol* and *salophen* have been given by many, while *aspirin* seems to be very efficacious and well tolerated; but, according to Dr. Gerest, *pyramidon* is equal in its effects to salicylate of soda. He administers it in doses of five grains every six hours or every four hours, according to the intensity of the affection, and continues it eight days after the fever has yielded.

Generally, he says, from the day following the administration of the pyramidon, a great improvement in the local and general symptoms takes place; the temperature falls almost completely, and gradually the physical signs disappear.

No accident of any kind was ever observed during the treatment; the only inconvenience is the production of sweating, but few patients complain of it, and in any case it diminishes rapidly, although the drug is continued. However, it would be well to abstain from giving it to consumptive and diabetic patients; in the former on account of the sweating, and in the latter because it increases the quantity of sugar eliminated by the urine.

### BLEEDING HÆMORRHOIDS.

The following will be found thoroughly trustworthy in this troublesome complaint:—

Cocaine, gr. ¼.

Solution of adrenalin (1 in 1,000), o.m.

Antipyrin, grs. v.

Cocoa butter, q.s.

For one suppository.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 18th, 1904.

In the *Korr. Bl. f. Schweiz. Aerzte*, Bd. 14, 1904, is an article on

### PRIMARY PERITONITIS IN INFANCY,

by Dr. E. Döbeli. He records a case observed by himself of primary purulent peritonitis, and remarks that he has been unable to find more than five other cases recorded in literature. His own case was that of a boy, 11 weeks old. It had been suckled by the mother from its birth to within four days of the commencing illness. The child was fed five times in the twenty-four hours, and vomited after every meal. It had three to four normal stools daily. The child had been very restless for some days before being taken to the polyclinic.

On December 26th the state was as follows:—Slightly furred tongue, temperature 37° C., weight 5 kgrm. The child was put to the breast and drank 40 grm. on the following day. The general condition had got worse—temperature 39° C., weight 4.900 kgrm. For the next few days the secretion of milk returned to the breast, so that the quantity sufficed for the infant. Constant vomiting at first of milk, then of bile matter. January 1st.—The child had not taken the breast from the day before. The last stool was on December 31st.

The kidney excretion ceased, and the child cried constantly. Face pinched, somnolence, continued vomiting of bile matter, but nothing fecal. Extreme meteorism, dulness in the dependent parts. The child cried aloud when its abdomen was touched. The vomiting not so severe after washing out of the stomach. There was a suspicion that an abscess had burst into the peritoneum, but the desperate condition of the child would not permit of any surgical interference. The child died at six in the evening.

The autopsy showed purulent peritonitis. On opening the abdomen a large quantity of thin, odourless pus mixed with lymph flakes escaped. The whole peritoneum, especially that over the visceral parts, was much injected, and showed numerous fibrinous deposits. The mesenteric glands were swollen. There was scarcely any other pathological sign; there was no perforation, the vermiform and its neighbourhood and also that of the umbilicus, were normal. The spleen was not enlarged, the liver and kidneys were healthy. The case was diagnosed as one of diffuse purulent streptomycotic peritonitis.

In a case described by Netter, in a child, a day old, there was also meningitis. The excitors were pneumococci. Also in a case of Perrin's, there were pneumococci in the pus.

In the cases adduced the infection most probably took place from the intestines. The danger of the passage of bacteria from the intestine into the blood was greatest in the first days of life. The so-called puerperal infection of children was most frequent during puerperal epidemics. Of course, any peritonitis starting from the umbilicus would easily be recognised.

In the *Arch. f. Experim. Path. und Pharmak.* is a paper by Breuer and v. Seiller on  
THE INFLUENCE OF CASTRATION ON THE BLOOD OF THE FEMALE.

The authors have endeavoured by way of experiment to determine the question of the influence of the ovaries in connection with chlorosis. As the thyroid and suprarenal capsules have undoubtedly an influence on tissue change, so the ovaries have been thought to have an influence in certain anomalies of constitution. Independent of their function of evolution, they have been credited with another function, that of an internal secretion that is capable of influencing tissue changes.

Experiments were made on young female animals by depriving them of their ovaries, and the experiments showed that the loss caused a decided change in the quantity of the blood in the form of diminished blood corpuscles and lessened quantity of hæmoglobin.

The diminution in the blood was only a passing one, and after a time the function of the ovaries appeared to be taken up by other organs. Whether the poorness of the blood in blood corpuscles was due to over-destruction or diminished regeneration could not be determined.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 18th, 1904.

### ANOMALOUS FORM OF JACKSON'S EPILEPSY.

At the Bohemian meeting in Prague, Vitek showed a man, æt. 17, who, eleven years ago, suffered from meningitis, which was followed by hydrocephalus. The first attack of Jackson's epilepsy occurred at the onset of the meningitis and repeated itself at intervals afterwards, always becoming shorter. The contractions commenced in the right lower extremity, gradually rising to the right upper extremity and right side

of the face, while the eye was twisted towards the left.

The most interesting point in this case was the invasion of insensibility, unconsciousness, biting of the tongue, involuntary passing of water as well as other genuine symptoms of epilepsy. It might be mentioned that after this meningitis amaurosis with atrophy of the papilla set in.

His interpretation of the course of the disease was that the meningitis in the first attack was the result of an inflammatory encephalic process of the central convolution, whereby an adhesion of the meninges and grey cortex of the brain became united. Finally, hydrocephalus formed in the subarachnoid space, tearing up the adhesions and increasing the number and severity of the attacks.

### GOUTY PARALYSIS.

Thomayer gave a very instructive *résumé* of the paralysis of gout, which, he affirmed, assumed very mysterious manifestations, occurring in the hands of the neuro-pathologist as epilepsy, hallucinations, aphasia, and paraplegia, which disappear as soon as the gouty symptoms appear. These phenomena are met with everywhere, and need not be described, although it might be pointed out that there are four varieties of this gouty condition requiring close observation.

The first and common form is where the paralysis recedes as soon as the gouty symptoms develop; the second has the paralysis concurrent with the gouty symptoms and disappears with them; the third has the paralysis long after the gouty symptoms have disappeared; while the fourth has the most peculiar anomaly of all by having paralysis of one extremity at the same time that the patient is suffering excruciating pain in the opposite extremity.

All these forms of paralysis must be recognised as temporary neuritis without disintegration of the nerve fibre, having their origin in a toxic agent acting on the periphery of the nervous system. It should be borne in mind that this toxic substance is not to be found in the urine no matter how careful an analysis has been performed. The speaker assured his hearers that he had repeatedly injected the urine of these patients into frogs and failed to elicit any symptom of the poison.

### SACH'S AMAUROTIC IDIOCY.

Heveroch presented two sisters, æt. respectively 2½ and ¾ years, with a family tendency to idiocy. The children, he related, were quite normal and healthy at birth, and continued so for six months. About this time convulsions appeared, which were followed by squinting and inability to steady the eyes or recognise anyone, although the development still went on. The muscles were soft and paretic, but not atrophied. Neither of the children could sit up after this time; neither could creep or walk, but lay helpless performing purposeless movements. Spasms occurred either voluntary or from external stimuli. Neither of them had evidently any sense of hearing or smell, although taste seemed to be present. No trace of intelligence was to be observed. The parents were perfectly healthy, but the history of the father's side was not satisfactory, where there was a history of alcoholism, epilepsy, hydrocephalus, and arthritis deformans to be found.

Both of these children differ from Sach's type of the disease in (1) being the offspring of Catholic children and not Mosaic; (2) the absence of the characteristic macula lutea hypercausis and sense of smell; and, lastly, one of the children had passed its second year without any promise of improving.

## EVOLUTIO PRÆCOX.

A large number of these precocious children are described as *menstruatio præcox*, but Jaroslav drew special attention to a child, æt. 6½, which he showed to the members as a remarkable case of premature development. At its birth it was much larger in size than its other two elder sisters, and also grew rapidly after it was born. In its fourth month the breasts became swollen, with a sanguineous discharge from the vagina; at the sixth month this was repeated, and has recurred regularly since every four weeks, continuing to discharge for three or four days at the period. The only exception occurred two years ago, after an attack of scarlet fever, when the menses were suppressed for six months. At the age of one and a half the hair was a considerable length on the pubes and in the arm-pits. The child now weighs 25½ kilos, or 4 stone 3 lbs., and measures in height 127 centimetres, or 4 feet 2 inches, and has all the appearance of a girl of 13 or 14 years of age. The breasts measure 14 centimetres in diameter, half spherical mammilla, well formed and dark coloured around, well nourished and the hymen *in situ*. The labia majora are pigmented and full; and *per rectum* a large uterus can be detected with a very large irregular spherical left ovary. The pelvis is wide; and the skiagraph gives a picture of a perfectly developed female of 18 years. The epiphyses of the ossia femoris are quite hardened, and the pelvic bones perfectly ossified and bound together. The pelvis measures: Distantia bi-spinalis, 24½ centimetres; bi-cristalis, 25 centimetres; bi-trochanterica, 24½; and the conjugata externa, 15 centimetres.

Jaroslav said the causes for these precocities were recorded as many, but few had the record of this case to show. Among the etiological factors were rickets, tuberculosis, bacterium coli, stimulating diet, heredity, and, finally, primary hyperplasia of the ovary.

## DILATATION OF COLON.

Braun showed a specimen of a dilated colon, which he had taken from a patient on whom he had operated for a distended sigmoid flexure which had hitherto defied every therapeutic device of injections, puncturing and stimulating. He concluded that operation and resection gave the best results in all such cases.

Wredel did not think that every case required such operative treatment, as he had recently treated three such cases of dilatation, although one had to be resected.

Madelung said he preferred laparotomy as a radical cure.

## INTUSSUSCEPTION AND OPERATION.

Israel described a case of intussusception which he had endeavoured to treat with water and air injections, but the invaginated bowel could not be kept from repeating the dislocation, which necessitated operation on the fifth day, after which the patient made a perfect recovery. Since then he had operated on two others by an extraperitoneal method, and left an anus preternaturalis, both of which seemed to be doing well.

## The Operating Theatres.

## ST. BARTHOLOMEW'S HOSPITAL.

OPERATION FOR PERFORATED GASTRIC ULCER IN A MALE.—MR. McADAM ECCLES operated on a man, æt. 28, who for two years had had continued indigestion with gradual loss of appetite. The patient was seized with an exacerbation of pain soon after his mid-day meal on the day before admission. He

vomited, but the ejected matters contained no blood. He immediately became somewhat collapsed, and had very great difficulty in reaching the hospital from his home, a quarter of a mile away. On admission, his pulse was 64, his temperature normal, but his respirations were somewhat quickened. The abdominal walls were held rigid everywhere, but especially so in the epigastrium. Pain over this region was very severe and radiated to the back of the left shoulder. The liver dulness was present, and there was no sign of free fluid in the abdomen. There was some uncertainty as to the diagnosis, but within a few hours from admission his temperature had risen to 101.6°, his pulse to 94, and his respirations to 28. Further, his liver dulness had given place to a resonance, and there was marked rigidity over the upper half of the abdomen. Mr. McAdam Eccles decided to explore. An incision was made four inches long in the middle line above the umbilicus. The extra-peritoneal tissue was œdematous. Gas escaped when the peritoneum was opened. The anterior wall of the stomach, which was not adherent to the parietes, was bathed with gastric contents. A small perforation, the size of the uncut end of a cedar pencil, was found close to the pylorus, but definitely to its left. The stomach wall in its neighbourhood was much thickened, and the surrounding peritoneum injected, and covered with a flake of lymph. Owing to the induration of the stomach wall about the site of the perforation, there was much difficulty in closing it because of the silk Lembert sutures tending to cut out. After some time, however, a satisfactory plication was accomplished, and an omental graft stitched over it. A thorough cleansing of all the surrounding area was carried out by sponging. No flushing was used. The wound was closed in the upper portion, but the lower was packed with sterile gauze. Mr. Eccles remarked that there were several points of considerable interest in the case. In the first place there was the fact that the patient was a male, for gastric ulceration in men is distinctly uncommon, and a perforated gastric ulcer extremely rare. Duodenal ulceration and perforation, he pointed out, were not so unusual in males. Again the extreme pain with intense rigidity of the upper part of the abdominal wall was a feature of great importance in the diagnosis, and this practically decided him in performing an exploration. The fact that the abdomen was opened and the aperture in the stomach wall found and sutured within six hours of perforation was greatly, he said, in favour of recovery. In the majority of perforations of the gastric and duodenal walls he believed it to be safer to simply plicate with Lembert's sutures, placed well beyond the site of perforation as well as over it, rather than to excise the ulcer and restore the continuity of the wall. The omental grafting also helped to secure good union. He considered that unless there was extensive extravasation of gastric contents, it was better to merely wipe out the escaped material and to avoid free flushing, which had a tendency to distribute rather than evacuate the irritating matters. It was not well, he thought, in these cases to completely close the abdominal wall for fear of possible leakage, and, therefore, a gauze drain should be left for the first few days, and its presence for that period would but slightly retard healing of the wound and convalescence.

The patient made an uninterrupted recovery.

## CANCER HOSPITAL.

**OPERATION FOR OBSTRUCTION OF THE PYLORUS.—PYLOROPLASTY FOLLOWED BY FURTHER CONSTRICTION.—GASTRO-ENTEROSTOMY.**—Mr. BOWREMAN JESSETT operated on a woman, æt. 46, for obstruction of the pylorus. The patient came to the hospital first in January, 1903; she then complained of constant vomiting, which had lasted more or less for two years; she could retain nothing. She had lost four stones in weight, at this time weighing seven stones. The stomach was greatly dilated and a somewhat hard mass could be felt to the right of the umbilicus. The succussion note was very distinct. The general aspect showed pinched features, with an anxious look, and the woman was very emaciated. There was little or no pain. She never had had hæmatemesis. Mr. Jessett opened the abdomen in the middle line between the ensiform cartilage and the umbilicus, withdrew the stomach and examined the pylorus, which was found to be thickened. He next made an opening in the stomach about two inches from the pylorus and passed in a finger. He could find no growth, but an old ulcer partly cicatrised was seen at the back of the pylorus. He could barely get the tip of the little finger into the pyloric orifice. He decided to perform pyloroplasty. The patient made an excellent recovery and remained well for some nine months, when the old symptoms began to return. Her weight was then eleven stones; since then she gradually lost two stones. She came to the hospital again fifteen months after the first operation. Her weight was then nine stones, and she had been suffering from constant pain. She had vomited up about half a pint of dark fluid three months previously. Mr. Jessett advised her to come into the hospital to have gastro-jejunostomy performed. This was done a month after. An incision was made in the right linea alba, and a loop of jejunum withdrawn through the opening with the stomach; these were united first by a circular continuous suture extending round the posterior parts, and through the serous and muscular coats. A free opening was then made into the bowel and the stomach, and the cut edges united by continuous suture passing through all the coats of both viscera. The suture which had united the serous surfaces was then continued round the whole opening. A few stitches were passed through the serous and muscular coats of the proximal end of the jejunum, fixing the gut to the stomach wall to prevent kinking. The abdominal wound was united in three layers, and the patient returned to bed. Mr. Jessett said that this case illustrated very well what many surgeons had reported—namely, that strictures of the pylorus operated on by pyloroplasty are very apt to become constricted again. It was interesting, he thought, to see how the patient had improved in general health and weight for nine months after the first operation; then the pyloric orifice again became constricted, and the old symptoms recurred, so that he would advise in all such cases that a gastro-jejunostomy should be performed in the first instance.

Six months after the last operation the patient is well.

THE influence of a fine September has already made itself felt in the mortality returns in a marked manner, both in town and in country.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 21, 1904.

**HOSPITAL ISOLATION AND SCARLET FEVER.**

THIS week we publish further contributions on the supposed value of isolation hospitals as preventives of scarlet fever, and we commend the arguments used to the judgment of our readers. They confirm the conclusions reached by the writers in the last two numbers of THE MEDICAL PRESS AND CIRCULAR, namely, that the whole subject of the utility of these hospitals is ripe for full and free investigation by an authoritative body. We hope to publish further communications on the same question, as we feel that the matter is one on which every particle of information available should be forthcoming. All over the country large sums of money are being spent by municipalities on the construction and maintenance of these institutions; indeed, the hospital is one of the largest items of the sanitary budget, and it behoves medical men who are intimately connected with the scheme to see that the money is used to the best advantage. At present it may be gravely doubted, in view of the evidence brought forward, whether the community is wise to burden itself with the maintenance for a period of many weeks of thousands of cases of scarlet fever. Unless it can be shown that the procedure affords a marked degree of protection from the incidence of the disease—an assumption that is, to say the least, doubtful—it is difficult to contend that its benefit is at all commensurate with its cost. It must be clearly borne in mind that the aim of isolation hospitals is only incidentally philanthropic, and that they were not primarily instituted to afford relief to sufferers from infectious diseases. Had they been erected for that purpose, their founders would never have left severe cases of measles and whooping-cough—diseases far more prevalent and fatal than scarlet fever is at present—to be nursed and tended in back kitchens and garrets,

while mild cases of scarlet fever receive every attention in hospital. The aim of the hospitals was to abolish scarlet fever from our midst, or at least to reduce it materially, and by their ability to accomplish this end they must stand or fall. Certainly, in the opinion of some of our contributors, they have been but qualified successes. Then, too, as to certain positive evils of these hospitals. There need be no hesitation in saying that the evils of segregation have shown themselves to a greater or less extent in all the large fever hospitals, in spite of elaborate care in construction and skilful administration. On the other hand, information is forthcoming from many of the smaller institutions to show that such evils are practically unknown in them, and that cross-infection of patients is of the greatest rarity. The suggestion naturally occurs that whilst the small hospitals have been useful and advantageous, the larger ones have not been so, and here again we see a fruitful line for investigation. No sort of conclusion can be entertained unless founded on the most complete information and on the widest data available. It has been contended that every medical officer of health should make his own inquiries, and, having satisfied himself that his hospital is doing good in his district, should rest content in that assurance. Surely this is a selfish view to take of the matter. Some towns and districts admit partial failure and positive evils, and it is for those districts that are free from them to allow the knowledge of their advantages to become of general utility. The kind of information that is needed is so broad and so varied that no inquiry would be likely to be successful that was not undertaken, not only by acknowledged experts, but by men of authority whose disinterestedness and integrity were above suspicion. Such an inquiry should embrace questions of construction, site, and disposition of hospitals; their principles of administration and their arrangements for dealing with doubtful and complicated cases. Besides these points, the experience of this country with regard to scarlet fever should be compared with that of those countries that do not isolate scarlet fever, and different towns, and different parts of the same town, should be compared as to the incidence of the disease in them. It might prove that whereas it hardly paid the community to segregate all their scarlet fever cases, yet it might be well to continue with the isolation of those that occurred in dairies, public institutions, and closely-crowded quarters of towns. And, again, it might be held that, having a diminished number of cases to deal with, there should be arrangements at all large hospitals for separating patients from one another in cubicles, at any rate in the case of young children. Without associating ourselves entirely with the views expressed by all our contributors, we hold strongly that they have made out a good *prima facie* case for investigation, and we should be glad to hear that a strong representative committee had been formed for the purpose. A Royal Commission has been hinted at, but the question has

hardly reached the point of public interest at which a Government can no longer hold back, and we think in the meantime the work could be done better in many ways by medical men.

#### MEDICINE AND PATHOLOGY.

It has been a necessary result of the growth of the sciences which are auxiliary to the practice of medicine that their pursuit has fallen into the hands of others than the practitioners of the art. Only a few years ago the physician regarded it as his own duty to examine, let us say, sputum for suspected tubercle bacilli, whereas nowadays he rarely performs such examination. Similarly, the surgeon who required the help of microcology in the diagnosis of a tumour formerly cut his section and himself examined it; but to-day a surgeon would be considered rash thus to rely on his own opinion. In all such cases it is now the practice to refer the suspected material to an expert in pathology, whose report is to be regarded as one of the principal factors in diagnosis. Following on this splitting-up of duties that formerly fell to one person, there is naturally a certain narrowing of outlook. The physician is more purely a clinician than formerly, and the surgeon tends to become more of an operator. Each is content, to some extent, to leave pathology to the expert pathologist. At the same time, the latter subject has grown to such dimensions that the pathologist can rarely be intimate with the clinical side of disease. The consequence of this separation of spheres of work is often, unfortunately, a certain lack of appreciation in each of the work done by the other. The pathologist is too apt to form his conclusions without taking clinical considerations into account, and indeed the physician or surgeon often demands his opinion without giving him any help from the clinical side. Nothing can be more absurd than to expect a pathologist from pathological evidence alone to decide, for instance, the exact nature of a tumour. The clinical history, however, taken in conjunction with the microscopic appearance, may be absolutely diagnostic as between, say, a sarcoma and an inflammatory swelling, or between a malignant and an innocent growth. It is only by combining, as far as possible, the visions from the two points of view that good results will be reached. The physician or surgeon, therefore, should never send material to a laboratory without giving at the same time a concise clinical history of the case. We have heard, indeed, of a pathologist receiving a drop of blood on a scrap of paper, and being asked to decide whether the cow whence it came was tuberculous; and it is not uncommon to receive material in some strong antiseptic with a request for a full bacterioscopic examination. "Science is One," said Socrates, and, in so far as the student of any branch fails to realise the connection of that branch with the tree of knowledge, in so far does he fail as a man of science.

### THE LONDON HOSPITAL AND HOSPITAL ABUSE.

THE abuse of hospitals is one of the standing grievances of the general practitioner. That this discontent rests on a solid foundation can hardly be doubted by any candid onlooker acquainted with the facts of the case. The enormous attendance of out- and in-patients furnishes in itself sufficient internal evidence of the indiscriminate relief obtained at the great general hospitals throughout the kingdom. In spite of generations of complaint on the part of the medical profession the evil is growing by leaps and bounds, and has of late years been increased by the adoption of the pay system by various great general hospitals. Needless to say, the system of part payment is likely to multiply abuse by offering a salve to the conscience of well-to-do folk who might otherwise possibly entertain some lingering scruples as to the moral justification of their acceptance of alms intended for the sick poor. It is of some interest to ask why so little has been done to meet the demands of the general practitioner as regards the loss he sustains through the laxity of the hospital authorities in excluding well-to-do persons from the benefits of which they are the stewards. The causes are complex. First of all the medical charities and the medical profession do not work together. The hospitals are engaged in an internecine conflict and in efforts at self-aggrandisement. Many private and non-medical interests are wrapped up in these institutions, together representing an enormous annual expenditure of money. It is not too much to say that the aim—natural if not excusable—of all such persons is to swell the funds of the individual hospitals and secure the maximum number of patients, regardless of the medical practitioners outside. It is a serious matter that this attitude is positively supported by the honorary medical staffs, who are induced to give their gratuitous services to many in- and out-patients perfectly well able to pay the moderate fees of the general practitioner. Much more might be written upon the subject, but the tale is somewhat trite, and its chief points have been familiar to generations of medical men. The great self-evident want is that of organisation in all ranks of the profession for the purpose of common support and defence. The East End (London) Medical Association—a strong local combination—has shown what can be done by firm and united action. For many years the administration of charity at the London Hospital has been called in question. The answer of the authorities has always been to ask for proof of abuse and to deny the existence of the same in general terms. The Society mentioned has furnished a number of cases of abuse of the London Hospital by well-to-do persons. The authorities of the hospital have acknowledged the existence of such abuse and have appointed an almoner to sift cases. The further suggestion, however, that medical men should come to the hospital to identify patients appears to be about as ridiculous and unpractical as it would be possible

to expect even from a hospital committee. It is likely that from the circumstances of the case abuse at the London Hospital, situated as it is in the midst of a poor population, is less than at most of the great general hospitals of the Metropolis. Now that the ice has been broken and the first step towards justice and conciliation taken by the hospital authorities, it is to be hoped that in combination with the East End Medical Association they will readjust the relations of the London Hospital with neighbouring practitioners. It is to be hoped, also, that the Association will be enabled to banish a system of patients' payments recently adopted at that hospital—a fact which, in our opinion, constitutes a serious blot upon a great charity. Since the publication of the London Hospital disclosures certain interviews, apparently authentic, have appeared in the daily newspapers. They purport to come from stewards and secretaries of other great London hospitals. For the most part they deny the existence of hospital abuse; one of those interviewed contrives to give a good advertisement of the pay wards in his own hospital; all ignore the general practitioner in contemptuous fashion. That is the kind of attitude to which medical reformers have become accustomed. It is only by extending organised attack all along the line that the general practitioner can ever hope to come into possession of his birthright, of which he is at present more or less deprived by hospital competition. The East End Medical Association should be the model and example of local societies throughout the United Kingdom.

### Notes on Current Topics.

#### Hans, the Thinking Stallion.

THE art of training the lower animals to perform tricks has long been popular with mankind, and though these feats are primarily intended to astonish and amuse, they have in many cases a scientific interest for the anthropologist and even the psychologist. As a rule dancing dogs and curvetting cats merely bespeak a certain amount of sympathetic perseverance on the part of the trainer, reinforced, one fears, by the lash, and a certain litheness of the muscular system of the animal. The performances of the anthropoid apes stand on a different platform. Sally, the chimpanzee, was taught to count up to five, an accomplishment entirely lacking among the inhabitants of Damarland when Mr. Francis Galton visited them. Similar proofs of intelligence in animals are mentioned from time to time, and the upholders of instinct as opposed to reason do not stand on anything like so secure a foundation as they did five-and-twenty years ago. The most remarkable of animals, however, seems to be Hans, the thinking horse, as he is called, who has been astonishing Teutonic audiences for the last few months. The horse is by no means one of the most intelligent of animals, and his usual tricks do not assume a higher form than that of waltzing on

his hind legs or caracolling at the bidding of his masters. There have, however, been one or two "calculating horses" who were able to tap out numbers with the fore-leg, but they have generally been noticed to keep a pretty sharp eye on the movements of the trainer, who probably possessed some means of indicating to them the requisite number of taps. But the performances of Hans have been so extraordinary that he has been submitted to an examination before a commission of thirteen experts, including Dr. Nagel, Professor of Physiology in Berlin, and Professor Stumpf, Director of the Psychological Institute. This commission has unanimously decided that Hans solves problems and answers questions as the result of a mental process analogous to that of the human brain, and that he is not influenced in any way by the acts or suggestions of his owner. If this really be true it is to be hoped that a full, signed account of the examination will be issued, for Hans will certainly deserve to rank with one of the seven wonders of the world. It is well to bear in mind the circumstantial reports showing that Hans acts under the influence of a wire-pulling attendant, and that the whole thing is a trick of the "spiritualist" order.

#### The Sequence of Disease Phenomena.

THE apparent want of regularity often noticeable in the processes of Nature is sometimes difficult to reconcile with the existence of definite laws. The principle of conformity to type is, however, so frequently departed from that the existence of biological "sports" is fully recognised. The manifestations of disease itself, though generally following the classical descriptions set forth in text-books, yet at other times differ so widely from the standard that a difficulty is felt in placing them under any known pathological group. Many a time the practitioner is confronted with an affection of which he may truly say, "I have never seen this described in the books!" The modes of onset and the clinical appearances of disease vary not less than the countenances of the patients. It is doubtful whether two cases of typhoid fever, for instance, are precisely identical in every particular, as regards either onset or course. Abortive forms, to which the terms "ambulatory" and "larval" are sometimes applied, are comparatively common. Certain affections adhere more or less strictly to a definite order in the appearance of their symptoms, as, for example, acute lobar pneumonia. Others, especially those of a functional character like hysteria, are a law unto themselves. A correct diagnosis is, no doubt, greatly facilitated when the disease conforms to a well-known type, but the sequence of morbid phenomena is often much disturbed, particularly in children. Dr. Adolph Rupp<sup>(a)</sup> has reported a most instructive case of measles in a young child, in which all the ordinary symptoms and signs of that complaint were reversed, the illness commencing with diarrhoea and bronchitis. The next day penumonic

consolidation was discovered, and the day afterwards the typical morbilliform rash made its appearance.

#### The Garden City.

PERHAPS the most practical piece of philanthropy of late years has been Mr. Booth's Garden City scheme, for it supplies what most philanthropic undertakings unfortunately lack—a sound commercial basis. The idea of a garden city, an open-air town, where every prospect pleases and man is made as little vile as possible, was a bold one, and was regarded as Utopian when it was first mooted. But the Garden City Company have to-day reached a point at which the success of their first city is assured, and the future holds many possible extensions of their scheme. The situation of this first city is an admirable one, standing three hundred feet above the sea level near Hitchin, and already the plan of the town is being mapped out and the sites are being taken up. Beauty and hygiene are the two factors that govern all the designs, and for the first time in history it seems as if beauty and hygiene are going to pay a dividend. Manufacturers are being attracted in numbers by the cheapness of land to transfer their works there, and already sufficient have been actually arranged for to give employment to twelve hundred families. The Garden City is thus assured of some five thousand inhabitants, a sixth of the number that the Company have fixed as the limit of the population. A beautiful stretch of country is being converted into a public park, whilst besides the model cottages that are being erected, a number of wealthy people are arranging for country houses on the outskirts of the town. The extraordinary feature of the project is the cheapness of everything, for land is to be obtained at a ground-rent of £10 per acre, and rates are to be fixed at 15 per cent. No wonder that the Londoner's mouth is being made to water at the prospect. We hope that the Garden City will achieve the success it so warmly deserves, but it is not likely to solve all the hygienic problems that beset it unless its plans and designs are submitted to careful medical supervision.

#### Incubation Period of Typhoid Fever.

AN experiment of great interest and importance was performed on a human being in Paris. Fortunately the anti-vivisectors cannot blame the doctors this time, for the seat of the experiment was the *corpus vile* of the experimenter. A nurse, wishing to put an end to herself, swallowed two tablespoonfuls of broth-culture of Eberth's bacillus, but, to her chagrin, no untoward effects followed at the time. On the third day, however, she was unwell with headache, though she had no fever, and by the sixth day she was obliged to take to bed with feelings of malaise and weakness in the lower limbs. The temperature the next evening was 38.6° C., and the following day she had epistaxis, several rose-spots, and pyrexia to the extent of 40.2° C. On the tenth day Widal's reaction was present. The attack

(a) *Amer. Journ. of Obstetrics*, August, 1904.

ran the ordinary course of typhoid fever of great severity, as may be gathered from the fact that not less than 176 baths were given. Now, although deliberate experiments on human beings are so monstrous as to be quite out of the question in any community, there is no gainsaying the fact that when they happen to be performed as in this case they afford information of the highest utility. This incident to the Paris nurse shows not only that Eberth's bacillus is the specific causative organism of typhoid fever, if any further confirmation were needed, but it throws fresh and unexpected light on the incubation period of the disease. Mr. Duflocq Voisin, who reports the case, attributes the shortness of this period—only two days—to the large number of bacilli ingested, but be that the case or not, we must now be prepared to admit that the minimum incubation time of typhoid fever may be very short indeed. We know that the bacilli in some cases take as long as three weeks to produce their effects, and that the usual period is about ten days or a fortnight, but it is now established beyond doubt that it is possible for them to set up typhoid fever in forty-eight hours.

#### Post-Diphtheritic Adiposity.

DIPHTHERIA is a disease that has many far-reaching results, and it is well known that convalescents from acute diseases often rapidly make up the loss of tissue they have sustained during their illness. But we venture to think that Miss Elizabeth Daltrey, æt. 9, of Bethnal Green, enjoys a unique distinction in being in possession of 10 stone 3 pounds of body-weight as the result of an attack of diphtheria. Apparently a normal child till overtaken with the disease, no sooner had it run its course than she began to put on flesh, or rather fat, at an alarming rate. Her waist now measures 42 inches, her chest 46 inches, and her arm 16½ inches—not a mean record for a child 4 feet 6½ inches high. The clue to her abnormal development seems to lie in her appetite, which is reported to be prodigious. She consumes as a rule twenty-four slices of bread and butter, besides beef, potatoes, and other necessities of life, every day. Of course this wretched little monstrosity is being exhibited by music hall proprietors to excite the wonder and admiration of their clients; it is too much to expect parents and impresarios to refrain from filling their pockets at the expense of public decorum. Instead of this child being placed under medical care and supervision she is being paraded nightly to excite the gapes of East End audiences—a state of things we should have thought that would hardly have been permitted by the magistrate who has to sanction her performance. Children of the proportions of Elizabeth Daltrey are the subjects of disease, and only a morbid pleasure can be derived from watching their clumsy antics.

#### Insanity in India.

IN the Annual Report of the Lunatic Asylums of Bengal recently issued, Colonel Browne gives us many particulars which are of interest by way

of comparison and contrast with the statistics of insanity in these countries. Just as at home, the asylum population is increasing year by year, and the figure reached last year in Bengal—1,348—is the highest yet recorded. Colonel Browne does not regard this increase as signifying an increase in the actual number of lunatics in the province, but rather as due to the more frequent resort to asylum treatment. If this view is correct, and it is borne out by the Census figures of 1901, which show a decrease in the total number of lunatics, then the increase in the asylum population is rather a matter for congratulation than otherwise. The principal cause of mortality was tuberculosis, and the death-rate was 100 per thousand—the highest in Indian asylums, the lowest being 76 per thousand in the Punjab. At Decca, where tuberculosis was most rife, there was considerable overcrowding, only fifty superficial feet of space being available for each patient. As in most asylums, mania is the most common type of insanity met with, but during the year no case of general paralysis of the insane was noted. It is by no means common in any Oriental race—a fact worth remembering in relation to the discussion as to its dependence on syphilis.

#### Diseases of Country Women.

AN interesting investigation has recently been conducted by an organisation in Canada known as the National Council of Women. Circulars were distributed to a large number of farmers' wives and daughters throughout Ontario containing queries as to the state of health prevailing in that class. A poll has thus been taken of the commoner diseases, and the two diseases which are said to have pre-eminence are rheumatism and "catarrh." The term rheumatism is probably used in a very wide sense, including all the chronic affections to which the name is given, most of which are due to the exposure to cold and wet to which these women are liable. In addition, the site of the farmer's house is often unsuitable, being damp and undrained. Associated with rheumatism mention is made of purpura, erythema nodosum and urticaria. "Catarrh" in Canada is applied in a somewhat narrower and more specific sense than in this country. It means usually a chronic pharyngitis, beginning very gradually, but often going on to an extensive thickening of the mucous membrane of the pharynx, spreading to the larynx, the nares, and not infrequently the Eustachian tubes. A common enough result is a troublesome deafness. The cause of the condition is obscure, but it is generally said to be the constant breathing of impure air in ill-ventilated rooms. This theory is supported by the fact that it is much rarer among the men than among the women on the farms, as the former spend much of their time out of doors. Among the diseases which appear with lesser frequency are dyspepsia and anæmia, while one sufferer returns her trouble as "that tired feeling." It is a pleasure to find consumption is not prominently mentioned.

### The Suckling of Infants.

THERE is no doubt that the practice of rearing children by hand is in many cases a result of the same distaste for parental responsibility of which we have heard so much in regard to the artificial prevention of conception. In the higher ranks of society it has always been unusual for the mother to suckle the child, but there is grave reason to believe that a similar reluctance is spreading throughout all ranks. A good deal of discussion on the subject has taken place in France recently, and the well-known charity of the "Gouttes de Lait" has been accused of encouraging the habit. Our readers will remember that this charity was established a few years ago to supply working women with suitable artificial milk for their children. It is now maintained that the comparative excellence of the supply encourages nursing women to wean their babies and feed them otherwise than from the breast. The consequence is that where a branch of the "Gouttes de Lait" has been established nursing is less and less practised by mothers. It is doubtless true, however, as is pointed out on the other side, that the conditions of modern life tend to make it more impossible for working women to give as much of their time to their infants as formerly. The post office, the telephone, the typewriting machine, not to speak of the factory, keep women tied to long hours of labour which render the nursing of an infant either an impossibility or such a drag as to prove a serious business embarrassment. In such cases, and in others where healthy mother's milk is unavailable, there is no doubt that the "Gouttes de Lait" is doing excellent work. At the same time the greatest care is necessary in its administration, and it is always to be remembered that the substitution of artificial for natural feeding is never to be made without the gravest consideration.

### Rubber Gloves.

IT has become so much the fashion to wear gloves while operating that there are doubtless many who merely follow the fashion without paying much attention to its underlying basis of reason. In doing so they are very liable to render their trouble futile by overlooking some simple precautions. The principal, though not the only reason for wearing gloves is that they, unlike the hands, can be rendered absolutely sterile. Nevertheless one often sees a surgeon, when preparing for an operation, wash his hands with a certain amount of care, probably less than he would take if he were not about to wear gloves, and then proceed to put on the sterilised gloves, using his hands freely in doing so. If his hands were sterilised by the washing, why proceed to wear gloves? If they were not sterilised, then the gloves have been thoroughly exposed to infection in the process of drawing them on. Or, again, if the gloves are floated in water or antiseptic solution, then a certain amount of fluid is bound to be left in the fingers. The skin soaks in this for a little, infects it, and a change of level discharges the fluid into the wound. It

is curious how often points such as these are overlooked even by careful surgeons, unless their attention is specially drawn to them. Dr. Howard Collins, of New York, who has given a good deal of care to the subject, (a) is convinced that gloves should always be worn dry, using sterilised starch or lycopodium as a lubricant. In drawing on the gloves nothing should be used except a couple of pairs of dressing forceps, and a little practice renders this easy.

### The Position of Gynæcology at the Meetings of the B.M.A.

OUR readers may remember that we drew attention to, and strongly criticised, the arrangements at the recent meetings of the British Medical Association, by which papers dealing with obstetrical and gynæcological subjects were brought before sections other than that devoted to the consideration of such subjects. We are glad to learn that the Council of the Association has adopted views similar to those which we expressed, and that it has decided that, in future, the allocation of papers to their respective Sections shall be subject to its directions. This decision means that gentlemen who desire to display their knowledge of special subjects must do so before the Sections devoted to those subjects, and not before some other Section which they may personally favour. To discuss the subject of hysterectomy before the Surgical Section of the meeting when a Gynæcological Section was in existence was about as suitable an arrangement as it would have been to have discussed the treatment of middle ear disease before the Medical Section. We can quite understand the desire of a general surgeon to gather every branch of special surgery into the Surgical Section, but we cannot understand the Association permitting such a course, unless it at the same time decided to abolish the Special Sections.

### The Children's Tooth-Brush.

THE need of systematic attention to the teeth, especially during childhood, is not by any means universally recognised. So it would appear, at least, from the deliberations of a certain rural board of guardians. The suggestion of one of their number that the children in their cottage home should be supplied with tooth-brushes was not only thrown out by the majority, but the proposal was actually ridiculed by a select few, among whom was the Mayor of a well-known watering-place, who considered that such luxuries would lead to greater degeneration of the race than that already existing. Hard crusts are all very well in their place, but what if the teeth are too decayed to bite them? The toast, made by others, that they themselves had never used such an essential article of toilet, nor their fathers before them, and yet had attained to a good old age, is unworthy of an assemblage of civilised folk. We wonder what the medical member of the board (if there were one) said at the

(a) *Medical News*, N. Y., August 20th, 1903.

discussion. Could those who look at the tooth-brush with contempt simply because they themselves happen to be blessed with a naturally perfect set of grinders pay a visit to the Dental Hospital and see for themselves the deplorable state of many people's teeth as a result of neglect, they would doubtless reconsider their decision. One need not go so far. Take the teeth, for example, of any number of school-children, presumably healthy, and the large proportion of those with imperfect dentition in which caries chiefly predominates will surprise those who have not previously paid any attention to the subject. The statistics of the medical officers to the School Board bear out this fact over and over again. Bad teeth and the accompanying oral sepsis contribute much to the physical degeneration. As a set-off, however, to such short-sighted policy, it is gratifying to note that another board of guardians has recently appointed a qualified dentist to look after the teeth of the children in their homes.

#### Pregnancy in Uterus Bicornis.

VARIOUS good authorities have stated that pregnancy does not occur in a bicornate uterus, but the dictum is shown by recent records to belong to the class of generalisations condemned by Bacon: "*Inductio per enumerationem simplicem ubi non experitur instantia contradictoria.*" Contradictory instances have, however, been found, and so the supposed law fails, but at the same time the recorded instances are so rare that they deserve notice when they occur. One of the best authenticated is a case recently published by Dr. Green of Boston. (a) During labour the uterus was seen to be divided into two distinct parts by a median sulcus, which became deepest at the fundus, and was accentuated by each contraction. On the right side the foetus was made out, while on the left a placental bruit was heard. After the birth of the child, a mass of the size of a normal uterus in the third stage remained toward the left, while a smaller one was felt to the right. Exploration of the uterus after the puerperium bore out the diagnosis. The sound only passed a short distance in the middle line, but slipped to one side or other. The cornu on the right side was five inches in depth, that on the left half an inch more.

#### The Brutality of Kindness.

To the outsider many of the professional acts of the medical man must savour of downright hard-hearted brutality. But it is kindness in reality akin to that of the parent who refuses to spoil the child by sparing the rod. The keen knife and the manipulations of the surgeon save many a limb and many a life. Were it not for the iron nerve of the trained men of medicine, both physicians and surgeons, the mortality of poor, maimed and suffering humanity would rise straightway to

the fever pitch of pre-scientific days. The refusal to recognise the necessity of subordinating the lower animals to the ultimate good of man in the experimental laboratory has led to the strange, sad, erratic, and contradictory cult of the antivivisectionist. Fanatics of that order eat boiled lobsters, blanched veal, driven grouse, grilled cod and salmon; decorate their hats with egret's feathers and stuffed humming-birds or gulls; flog their horses and put them in bearing reins; shoot trapped pigeons, hunt tame deer, and commit many acts of wanton cruelty that would make the average thinking medical man shudder to contemplate. Yet they, sooner or later, become the patients of the men they so bitterly denounce. A fortnight ago an amusing instance of misplaced indignation was divulged at an East London inquest. Some maternity students from the London Hospital were accused of behaving with great cruelty to a baby. It appears that they were really trying to animate a gasping new-born babe by the Schulz system of respiration, which involves swinging the child about in the air. The jury found that death was due to insufficient expansion of the lungs, and the students accordingly returned to their scientific labours, to use the language of the police-court reporters, "without a stain upon their characters."

#### Reversed Peristalsis of Intestines.

THE question of reversed peristalsis in the alimentary canal is both interesting and also of considerable practical importance. Partial peristalsis is seen in the curious power of regurgitation of food from the stomach to the mouth possessed by some persons, a faculty more or less closely analogous with the herbivorous habit of "chewing the cud." Peristalsis is also concerned commonly in bilious vomiting. Another familiar example is faecal vomiting in the later stages of intestinal obstruction. Reversed peristaltic action of the whole alimentary canal, however, is extremely rare. A most interesting instance recently occurred in a patient at the Westminster Hospital under the care of Dr. William Murrell for ulcerative colitis. The malady was cured by the injection into the bowel of argyrol, a chemical combination of synthetic vitellin containing 30 per cent. of silver. When about five pints of solution had been injected, the patient being in the knee and elbow position, fluid was seen pouring from his mouth. The same sort of thing happened at subsequent injections, and it was proved by chemical tests of the vomited fluid that the unaltered silver had passed through the whole length of the canal from the rectum to mouth. For some reason or other the ileo-cæcal valve had failed to exert its usual action against backward pressure from the colon side. The case is of value, as it is an accurate and scientific record of a rare clinical occurrence.

#### An Extraordinary Action for Malpraxis.

A REMARKABLE action for damages is pending in the French Courts, the defendant being a well-known surgeon, Dr. J. B. Fort. We gather that

(a) *Boston Med. and Surg. Journ.*, June 9, 1904.

Dr. Fort undertakes to bring about dilatation of pyloric obstruction by electrolysis, apparently on the lines followed some years since in the treatment of urethral stricture. He makes use of an insulated electrode, with a flexible gum-elastic end as a guide. This he introduces through the œsophagus, and in so doing, in this particular instance, the "guide" broke off. As there was no reason to anticipate any trouble from the passage of this pliable foreign body through the intestines matters were allowed to take their course, but a few days later the patient was seized with violent abdominal pain and promptly succumbed. Nothing more was heard of the matter for some months, when a discharged assistant of Dr. Fort's wrote to the widow informing her that her deceased husband had been the victim of a surgical mishap, whereupon the widow instituted proceedings to recover damages. The body was exhumed, and was carefully examined by several experts in the presence of the defendant. The terminal portion of the sound was discovered in the intestine, not apparently having caused any local injury. If this version be correct it is difficult to see what ground for action there can be, and it seems highly probable that the proceedings will end in a non-suit.

#### No Public Mortuary.

It is a lamentable fact that many districts, some of them densely populated, both in town and country, are unprovided with a public mortuary. The way out of the difficulty has been hitherto met in the time-honoured way by taking off the body of anyone found dead to the nearest public-house. But even the "trade" may revolt and turn away from its doors the passive harbinger of "crowner quests." Such was the case at Maidenhead the other day when a body was found in the river. After being refused by several publicans, the body was deposited on an island for several hours among the rushes, but room for it was eventually found in an unoccupied public-house belonging to the Corporation. Can it be believed that Maidenhead, the wealthy, the populous, the picturesque river resort, is without a public mortuary? Such, however, is the fact. It would be as well to insert a clause in the next Public Health Act making it compulsory on all local sanitary authorities to provide adequate mortuary accommodation in their districts.

#### The Origin of Elements

SIR WILLIAM RAMSEY is not the man to boast or speak prematurely, and an announcement he made at a dinner given to him by the Society of Chemists in New York cannot but stir the curiosity and interest of the whole scientific world. Sir William stated that he believed chemistry to be on the eve of discovering the origin of elements—a conclusion he had come to as the result of his own researches and experiments. He has recently discovered a new substance of such properties as to place the whole question in a new light, and he hopes to

publish his work shortly to the world. It is tantalising to be told so much and yet have to wait some months before being admitted to the whole secret, but one may safely trust the discoverer of argon and helium not to buoy his admirers up with false hopes. The science of chemistry has moved with rapid steps of late years, and the wonders of radium seem likely to lead to conceptions of the origin of matter that would have been regarded as rank heresy ten years ago.

#### PERSONAL.

H.R.H. THE DUCHESS OF ALBANY will open the new operating theatre at the National Hospital for the Paralysed and Epileptic, Queen Square, London, on October 8th.

DR. W. A. BURT has been elected President of the Ontario Medical Association for the coming year.

MRS. BARROW has endowed a bed in the Liverpool Royal Infirmary at a cost of £1,000, in memory of her late husband, Mr. William James Barrow.

DR. SCHWENINGER, who was at Friedrichsruh in attendance on the late Prince Herbert Bismarck, was for many years the physician of the Iron Chancellor.

PROFESSOR KOCHER, of Berne, will preside over the first congress of the Société Internationale de Chirurgie to be held in Brussels in September, 1905.

ON behalf of the David Lewis Trust, Mr. B. W. Levy formally handed over to the Lord Mayor of Manchester, as representative trustee, the title-deeds of the Saalbridge Colony for Epileptics.

SURGEON-MAJOR T. E. F. MCGEAGH has resigned his commission in the Honourable Artillery Company of London, and retires into the Veteran Company, with permission to wear the uniform of the corps.

SIR WILLIAM MCGREGOR, who recently kissed hands at Balmoral on his appointment as Governor of our oldest colony, Newfoundland, just thirty years ago took his M.D. degree at the neighbouring University of Aberdeen.

THE appointment of Dr. Herbert M. Ellis, Inspector-General of Hospitals and Fleets, to the position of Director-General of the Medical Department of the Navy, in the place of Sir Henry F. Norbury, whose term of office has expired, is now officially announced.

DR. LORRAIN SMITH, formerly Professor of Pathology in Queen's College, Belfast, who has been appointed Professor of Pathology and Pathological Anatomy in succession to Professor Delépine, in the University of Manchester, will open the Medical Session at the latter on Monday, October 8th, by delivering an inaugural address.

SISTER MARGARET BROWN, the English hospital nurse nursing the Queen of Italy, was specially selected for the post by the Matron of Queen Charlotte's Hospital, where she was for some time a sister. Needless to say, in addition to her high professional qualifications, she possesses tact and all the other qualities which are essential in a good nurse.

PROFESSOR MORISANI, the Queen's accoucheur, is a well-known person in Italy, for one reason, on account of his exceedingly dwarf-like stature. The Professor, who lives at Naples, has a son in the same profession as himself, and almost of the same size.

## Special Correspondence.

[FROM OUR SPECIAL CORRESPONDENT.]

## SCOTLAND.

**EDINBURGH UNIVERSITY AND DEGREES IN VETERINARY MEDICINE.**—It is a matter of public knowledge that for some considerable period negotiations have been going on between the Town Council, as trustees of the Royal (Dick) Veterinary College, and the University authorities in reference to the question of the granting of degrees in veterinary science. The position of matters now, as explained in an evidently authoritative article in the *Scotsman*, seems to be somewhat as follows:—The Dick College, founded in 1823, is apparently the only endowed institution of this nature in the country. It was affiliated to the Royal College of Veterinary Surgeons of London on their incorporation in 1844, and, since the death of its founder in 1866, has been under the guardianship of the Town Council of Edinburgh, by whom it was remodelled in 1886, so that now the whole tuition required is given in one compact, centralised building. The curriculum, formerly a two years' one, now extends over four winter sessions of thirty weeks, leaving the summer free for practical work in the country. Each group of subjects has to be "passed" in before further attendances qualify for subsequent examination—a provision which many of us would have the medical curriculum imitate. Students failing for more than a year without reasonable cause are permanently disqualified. Not very long ago the prospect of a largely increased endowment of veterinary science appeared. Mr. McAllum, a veterinary surgeon in Edinburgh, offered £15,000 to endow a chair of pathology and bacteriology; Miss Dick, the sister of the founder, has bequeathed about £23,000, part of which is for a chair of comparative anatomy; and further moneys are expected to fall in. Further, the New Veterinary College, which hived off from the Dick, has been absorbed into the new school at Liverpool, and no longer needs to be considered in any amalgamation scheme. The projected scheme of the Town Council and University contemplates a new Conjoint Administrative Board, and the removal of the college from the guardianship of the Council, a body obviously unfitted to manage such an institution. The University has issued a draft ordinance somewhat on the lines of graduation in medicine, with Bachelor's and Doctor's degree in veterinary science. The preliminary examination is to be the same as for medicine, *i.e.*, a higher standard than the existing one, and the course covers the subjects required by the College of Veterinary Surgeons *plus* heredity and the general principles of breeding. Before graduation, the candidate must be registered as a veterinary surgeon. One of the special difficulties is that veterinary registration is under a one-portal system, and two sets of examination fees will require to be paid, and two examinations passed unless some arrangement can be come to whereby the College examinations are, in the case of University candidates, accessible to university examiners.

**MATERNITY WORK IN EDINBURGH.**—The Milne Murray Lodge, which is now open for the reception of students, will greatly enhance the possibilities of getting a sound practical training in obstetrics in Edinburgh. The Lodge is close to the Maternity Hospital, and is in telephonic communication with it. Twelve students are accommodated at one time, and the usual period of residence is a month, each during that time easily overtakes his six cases. As a matter of fact, we believe that, besides these extern cases, the men during the past month had the opportunity of seeing nearly forty confinements, most of them abnormal, a great advance on anything practicable hitherto.

JOHN DALE TUCKER, stated to be an M.D. of Pennsylvania, U.S., was fined £10 and £5 costs on each of two informations before the Liverpool magistrates on Saturday for affixing the name of Dr. John Gould to two death certificates.

## THE DIMINISHING BIRTH-RATE.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—The discussion on this important subject has been up to the present somewhat disappointing. As a layman, after carefully following up the original articles and the subsequent letters, it seems to me that Dr. Walsh pointed out a serious flaw in Dr. Taylor's paper in the omission of illegitimacy figures from the total birth-rate. Then "LL.D." exposed an error in Dr. Walsh's figures, in answer to which the latter says the mistake does not affect his main arguments. Several concrete examples have been brought forward by correspondents asking Dr. Taylor whether his universal law of unrestricted families applies to their particular cases. The answer they have obtained can hardly be called satisfactory, and it certainly seems to me that Dr. Walsh's main criticisms have yet to be answered. The matter stands here for the moment. I sincerely trust more light will be forthcoming from the medical profession before it is allowed to drop. Why should good, struggling, sensible, kindly citizens be asked to bring up children with no prospects better than those of the streets and the workhouse? What is the value of abstract and ill-supported ethical theories to them?

I am, Sir, yours truly,

L. W. HUDSON.

Herne Hill, S.E.

## THE LUNACY QUESTION.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—I have no desire to discuss this question beyond Dr. Robert Lee's point as to our incapacity in defining insanity. The apparent difficulty in arriving at an acceptable definition consists in the fact that such diverse views are held as to what constitutes insanity, and so long as this exists it is obvious no unanimity or concurrence of opinion can exist. For example, a case was recorded a few days ago at an inquest on the body of a drowned sailor. It transpired that a delusion, common among sailors, had existed in the mind of deceased, that learning the art of swimming created an unfavourable omen as to fatality in drowning—a delusion not altogether harmless. Now, theoretically, one person might regard this as evidence of insanity, and another the reverse. Certainly, neither could define it as *legally* insane. Further as medical men, we are only called upon to certify insanity for legal purposes, and with this idea I ventured to define it in your columns recently "as a morbid condition of mind requiring supervision." Dr. Lee will observe that I do not commit myself by saying even legal supervision, which would necessarily at once subject a person to the hands of the law, whereas on the other hand, if we suppose, say, the validity of a will on the ground of imbecility or otherwise were questioned in a law court, the issue, as far as I conceive, would be determined on the definition in question one way or the other. Dr. Lee, who also observes that we are not required to define insanity as applied to any given individual in a lunacy certificate, which I so far agree is impracticable, because we do not understand mind sufficiently as he rightly suggests. We are only asked to *describe* the case in the lunacy form, and not to define insanity therein. Granted the apparent difficulty in agreeing to a definition as to what constitutes insanity, surely all specialists are in accord on one point, and that is in regard to the insane requiring the interposition of the law, and it is upon this idea I submit they must found their definition.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, September 8th, 1904.

### Obituary.

#### MR. ISAAC HARTHAN, M.R.C.S.ENG.

We regret to announce the death of Mr. Isaac Harthan, surgeon, who died at his residence, Blythewood, Parkfield Road, Didsbury, on the 5th inst. He retired from practice some years ago. Formerly for a long period he followed his profession in Hulme, and lived in City Road. Mr. Harthan became a member of the Royal College of Surgeons in 1856 after studying at Liverpool.

#### HENRY ARTHUR BENHAM, M.D., OF BRISTOL.

We regret to announce the death of Dr. Harry Arthur Benham, the medical superintendent of the asylum at Stapleton, at that institution on the 14th inst. He had been in indifferent health for some months past and, therefore, although his death was sudden, it was not entirely unexpected. The cause is stated to be heart failure. The deceased succeeded Dr. George Thompson on that gentleman's retirement in 1890 from the asylum, and with which he had been connected as assistant medical officer for some eight or ten years, and he had therefore put in over twenty years' service there. He was in his fiftieth year. A strong Conservative, he took a keen interest in politics, but was precluded from taking any active part in them owing to his position. He was an enthusiastic Freemason, and had held several prominent offices in the Order. He took his M.D. at Aberdeen in 1883. He was a lecturer on mental diseases at the University College, Bristol, and a member of the Council of the Medico-Psychological Association of Great Britain and Ireland. From time to time he made valuable contributions to the medical papers on his special subject. His father came of an old Bristol family. His only brother was also a medical man, but he died some years ago while abroad. He will be mourned by a large circle of friends, and especially amongst his professional and Freemasonry brethren.

#### CHARLES WILLIAM IZOD, M.D.

The death took place last Friday, at Whitehall Court, Westminster, of Dr. Charles William Izod, who for many years was medical adviser to the members of the French Royal Family during their residence at Claremont Palace, Esher, and latterly to the Duchess of Albany. He was also present at the death of Queen Amelie and the Duchesse de Nemours. Dr. Izod, who practised for fifty years in Esher, was, on the occasion of his jubilee, presented with a testimonial by the Duchess of Albany. His qualifications were M.R.C.S. Eng., taken in 1846; L.S.A., 1847; and L.M.Dub.

#### EDMUND CARVER, M.D.

DR. EDMUND CARVER, formerly demonstrator of anatomy at Cambridge University Medical School, but who had retired from practice, died on Wednesday at Torquay at the age of eighty. Dr. Carver was admitted a Member of the Royal College of Surgeons, England, in 1848, and a Licentiate of the Society of Apothecaries the following year, having professionally studied at University College Hospital Medical School. In 1854 he was elected a Fellow (by examination) of the Royal College of Surgeons, in 1858 graduated B.A. from St. John's College, Cambridge, in 1859 took the M.B. degree, and in 1866 proceeded M.A., but only took his M.D. in 1891. Besides being Demonstrator of Anatomy at Cambridge, he was Surgeon and afterwards Consulting Surgeon to Addenbrooke's Hospital, was a Fellow of the Cambridge Philosophical Society, at one time a President of the Cambridge Medical Society, and was a retired Surgeon-Major of the Cambridge University Rifle Volunteers. Dr. Carver had also been House Surgeon to University College Hospital, Gower Street, Resident Clinical Assistant at the Consumption Hospital, Brompton, and Surgeon to the Huntingdon County Hospital and the Hunts Rifle Regiment Militia.

#### FLEET-SURGEON JOSEPH WOOD, R.N., M.D.

THE death took place at Glengall, Hurstpierpoint, on the 5th inst., of Fleet-Surgeon Joseph Wood, R.N. (retired), at the age of 62. Mr. Wood, who took the degree of M.D. of Edinburgh in 1864 and L.R.C.S. Edin. and L.M. in 1866, joined the service in 1869, became staff-surgeon in 1880, and fleet-surgeon ten years later, retiring in 1893. He was surgeon of the *Himalays* during the war against the Zulus from 1877 to 1879 and was awarded the Zulu medal.

#### SURGEON-GENERAL JAMES JAMESON, C.B.

SURGEON-GENERAL JAMES JAMESON, C.B., died on Tuesday last at his residence, Newlands, Eltham. The son of Mr. William Jameson, of Ladeside, Kilbirnie, N.B., he was born in 1837, and was therefore 67 years of age. He became an M.D. of Glasgow University in 1865, and, having entered the Army Medical Service as Assistant Surgeon in November, 1857, he became Surgeon in March and Surgeon-Major in April, 1877. Surgeon-Colonel in 1888, and Surgeon Major-General in 1893. In May, 1896, he was promoted to be Director-General of the Army Medical Service, which appointment he held till 1901. Surgeon-General Jameson was made a C.B. in 1897, was honorary surgeon to the King, and a Knight of Grace of the Order of St. John of Jerusalem. During the Franco-German war of 1870-71 he served with the English ambulance. He married, in 1864, a daughter of the Rev. Robert David Cartwright, of Kingston, Canada.

#### COLONEL JOHN HENRY BEATH, M.D., C.B.

THE death was recently announced at Stirling of Lieutenant-Colonel John Henry Beath, M.D., C.B., in his seventieth year. He was a son of the late Dr. Andrew Beath, of Stirling, and was educated at the High School of that town. Later he graduated M.D. of Edinburgh University. He received in 1857 an appointment on the Medical Staff and served on it during the Indian Mutiny, being present at the siege and capture of Lucknow. In 1859 he joined the 3rd Foot (The Buffs), and was with his regiment in the China war of 1860. Colonel Beath's foreign service extended over fourteen years, his last campaign being the Egyptian expedition in 1882, when he was mentioned in one of the despatches of Sir Garnet Wolseley in the following terms:—"Surgeon-Major J. H. Beath, M.D., has been brought to my notice for some special favour, and I am glad to have this opportunity of recommending so zealous and hard-working an officer." Queen Victoria accordingly conferred upon Dr. Beath the Order of the Bath, and gave him permission to accept and wear the insignia of the Order of the Medjidieh, which the Khedive had conferred upon him. For ten years he held the garrison appointment in his native town of Stirling, from which appointment, owing to failing health, he retired only two years ago.

### Literature.

#### PRYOR ON GYNÆCOLOGY. (a)

AFTER reading the title-page of this work expectations were raised which were subsequently destined to be agreeably disappointed. We looked forward with no undue degree of pleasure to reading one of the latest additions to gynæcological text-books—innumerable as these seem to be in America. Yet, Dr. Pryor's reputation as a distinctly original worker in the field of operative gynæcology is by no means confined to his own land, and we were somewhat surprised that he should have added another to the student's already crowded choice in the matter of text-books.

(a) "Gynæcology": a Text-Book for Students, and a Guide for Practitioners. By W. E. Pryor, M.D., Professor of Gynæcology, New York Polytechnic Medical School, &c. London and New York: D. Appleton and Co., 1903.

But the title is the only part of this suggestive work which we could willingly dispense with. It is somewhat of a misdirection, for Dr. Pryor has given us a valuable addition to gynecological literature which is, however, from the student's or examination point of view a very poor text-book. But the book has a more abiding interest than any mere examination guide; it is a personal document which deals, if briefly, always suggestively, with some of the chief problems of modern or surgical gynecology.

This point of view being kept in mind, we can understand the omission, noted in the preface, of such subjects as bacteriology and pathological histology—subjects which, however, we could nowise accept as properly excluded from the pages of a work intended primarily as a student's text-book, or even for the guidance of the average practitioner. In our mind it is certainly debatable whether the gist of Dr. Pryor's message, which is essentially one to specialists—might not have been better conveyed in the form of a book of essays on technique in modern gynecological work. In any case it is true to say that this book—or much of it—will prove useful and interesting exactly in proportion to the previous personal knowledge and experience of the reader. We are convinced that the proper reader will turn again and again to its pages, not necessarily for agreement, but for views which are founded on a large and well-studied experience, and which are always clearly and suggestively stated. It is only needful to add that the illustrations and general get-up of the book are admirable.

#### SODDY ON RADIO-ACTIVITY. (a)

As the author observes in his preface: "The discovery of this new property of self-radiance, or 'radio-activity,' has proved to be the beginning of a new science, in the development of which physics and chemistry have worked together in harmony." The pioneer in the chemical development of the subject was, as is, of course, well known to all readers, Madame Curie, and our author places prominently before us the less universally familiar fact that "On the physical side, the brilliant and elaborate researches of Prof. Rutherford, at first mainly with thorium—an element which, like uranium, is so feebly active that it had been studied for a century before its radio-activity was discovered—paved the way for a complete and general theory of the cause and nature of the new property." The fundamental basis of this theory is that the *radio-active* elements are in a process of evolution (or devolution) towards lighter and more stable forms; that they are proceeding in this direction by a line of continuous and explosive disintegration of the constituent atoms; and that the fragments thus set free are spontaneously ejected in directly eccentric courses, and thus constitute the characteristic "radiations." The recent discovery of the continuous production of elementary helium from radium is, of course, a direct experimental confirmation of this theory.

The study of the subject of radio-activity has opened up new and unexpected views of the constitution of matter. It has "burst up" physically and metaphorically the previously indivisible "atom." As we ourselves could never picture to our unscientific fancy such an entity as a finally indivisible atom, we cannot pretend to lament its scientific extinction. And, as the Daltonic atom was but a chemical adaptation of the ideas of Democritus on the constitution of matter, so the discoveries of M. Becquerel and Madame Curie carry us back in imagination to the conceptions of Thales, when the first of Greece's famous roll of wise men taught his disciples that all forms of matter were ultimately reducible to a single element. Although the physico-chemical "Volapuk" of the present genera-

tion may not agree to recognise a single and universal basis of matter—whether under the name of *helium* or *hydro*, or *moisture*—the fact is unquestionable that the general trend of recent physical and chemical discovery has been to make scientists suspect, if not actually believe, its essential unity.

Of course, the great practical interest which the new science of radio-activity possesses for medical men is its promise in the broad domain of therapeutics—especially in the section devoted to the treatment of the hitherto hopelessly intractable forms of carcinoma, sarcoma, and tuberculous disease. In this connection, and on this account, we heartily welcome Mr. Soddy's work, as an excellent introduction to the study of the subject. And as no science is really foreign to medicine—not even the so-called science of metaphysics—we strongly recommend this volume to the attention of our readers. The intense interest attached to scientific research and discovery is—surely should be—the silvery margin of the too frequently clouded aspect of a medical career; and, although the consciousness of the possession of knowledge hourly approximating to that of the angels may offer but cold consolation to a dispensary doctor during his hill-side pilgrimage of twelve or fifteen miles in a blinding and petrifying blizzard, it will surely give him in his house of rest that soothing conscientiousness of the high-minded performance of the noblest duties allotted to humanity—those in which man approaches most closely to the thoughts and actions of the "Divine Exemplar" Himself.

#### KIRKBY'S PRACTICAL PRESCRIBING. (a)

PRACTICAL pharmacy is in danger of becoming a lost art. Most modern medical practitioners would seem to have but little genius for dispensing, and with the present vogue for factory-made medicines medical students have but little inducement to devote much time or attention to the practical work of the pharmacist. But it is most necessary that everyone who embarks on the practice of physic should at least be able to avail himself of the adequate resources of his national Pharmacopœia. Unfortunately, there are good grounds for the oft-repeated complaint that present day medical students receive an education which is defective in so far as it relates to the writing and compounding of prescriptions.

The admirable little work which Mr. Kirkby has prepared is conveniently suited for the needs of the average student. It is based on a course of practical prescribing and dispensing elaborated by the author for members of the Manchester Medical School.

In design, execution and general suggestiveness, it merits high praise; and it may be expected to become popular, not only in the Victoria University, but in other centres of medical study.

The work is divided into convenient sections dealing with various methods, preparations, and forms of administration. In the section dealing with the forms of administration and incompatibles, all the preparations of the British Pharmacopœia and of the Formulary of the British Pharmaceutical Conference are mentioned, together with their doses.

A highly commendable feature of the work is the presentation of dispensing exercises which should be of much service to teachers as well as of assistance to students.

The forms of administration, solubilities and incompatibles of the chief official and extra-official drugs are given in convenient alphabetical arrangement, and should prove invaluable for the purposes of rapid reference.

There is also a useful collection of the words and phrases used in prescription writing, but the author has wisely reversed the customary arrangement, since,

(a) "Radio-Activity: an Elementary Treatise from the Standpoint of the Disintegration Theory." By Fredk. Soddy, M.A., Lecturer on Physical Chemistry and Radio-Activity in the University of Glasgow. With Forty Illustrations. England: The Electrician Printing and Publishing Co., Ltd.

(a) "Practical Prescribing and Dispensing for Medical Students." By William Kirkby, sometime Lecturer in Pharmacology in the Queen's College, Manchester. Pp. 169. Manchester: Sherratt and Hughes. 1904.

as he points out, the prescriber usually wishes to know the Latin equivalent of the English, and not *vice versa*, as is the case with the dispenser.

The work appears to be peculiarly free from blemishes and particularly put in practical detail. It is manifestly the work of one who is a skilled chemist, and an expert pharmacist, and who knows not only the requirements of the modern student but the best way in which his needs may be met.

We commend the work to both teachers and students.

#### DAWSON TURNER'S MEDICAL ELECTRICITY. (a)

THE rapid appearance of a fourth edition of this excellent book is in itself sufficient evidence of its excellence and popularity. As might be expected by those who have followed the trend of modern electrotherapeutics a good deal of attention has been paid to the use of sinusoidal and high-frequency currents. It is to the latter part of the book that many interested in electrical matters will at once turn. Under the heading "Therapeutic Applications" is a short but good summary of what has hitherto been done by the use of the high frequency currents. The wide divergence of the morbid conditions that are thereby relieved or cured, and the general nature of the description, register the undeveloped stage of this modern method. Dr. Turner quotes the words of a contemporary author who says:—"There can be no doubt that in high-frequency currents we have a method of treatment of distinct value. Their power of service is marked in functional nervous disturbances and in localised vascular dilatations, but their influence over diseases of the skin suggest also that they are capable of profoundly modifying general metabolism, and that they will in time be found to have a wide range of application in the treatment of diseased conditions." The remarkable result obtained in the treatment of piles and of dilated stomach might, in our opinion, have been with advantage somewhat emphasised in Dr. Turner's account. The whole of the book has been revised in the present edition and thirty fresh illustrations have been added. We echo cordially the author's hope that the tide of unqualified electrical practice will ere long be stemmed, and that the day of the instrument-maker, the nurse, and the amateur empiric will soon come to an end. Certainly the writing of good books, such as that of the author's, will help us on the road to better things.

#### GIBBONS ON REFRACTION. (b)

THE author in his preface states that he has attempted to supply students of ophthalmology with the practical information needed upon the various subjects treated.

The deductions from the various formulæ used in optics have been simplified and inserted. Whilst falling in with the accepted custom of omitting the more purely mathematical treatment of the subjects, he considers that the student should be familiar with the physics involved for the proper understanding of the subject, and consequently much of the book is occupied by the explanation of the physical phenomena met with. The author "feels that the new material and diagrams the work contains justifies its publication, so offers no apology for adding one more to the numerous books upon the same subject."

The title of this most readable and excellent dissertation on the Refraction of the Eye, is rather misleading, for it does not deal with any of the conditions usually classed as "diseases of the eye," and any one who purchases it expecting to find a description of the diseases of the eye, will find his mistake. It is a

(a) "Manual of Medical Electricity." By Dawson Turner, B.A., M.D., F.R.C.P. Ed. Medical Officer in Charge of Electrical Department in the Royal Infirmary, Edinburgh, &c. Fourth Edition. London: Baillière Tindall and Cox. 1904. Price 10s. 6d net.

(b) "The Eye, its Refraction, and Diseases. The Refraction and Functional Testing of the Eye. Complete in itself, in twenty-eight chapters, with numerous explanatory Outlines and Diagrams." By Edward E. Gibbons, M.D. Pp. 472. New York: The Macmillan Company. 1904.

treatise on the perfection and accommodation of the eye, and the methods of functional testing, &c., but in no sense a treatise on ophthalmology, "complete in itself," as the title says. With this warning we can recommend this most carefully prepared volume to the notice of all those who require a well printed, profusely illustrated, and intelligently written treatise on the subjects dealt with.

#### ORTHMANN ON GYNÆCOLOGICAL PATHOLOGY. (a)

WE congratulate Dr. Roberts on the manner in which he has translated this valuable little work into English. Gynæcological pathology is a subject which has for some unaccountable reason been somewhat overlooked in this country. The works on general pathology pass over the special pathology of the female genital organs with a cursory notice, and gynæcological hand-books and text-books are more occupied with the therapeutical and surgical aspect of gynæcology than with its pathology. For this reason, the want of a reliable work dealing with the subject is distinctly felt, and this English edition of Orthmann's work will, we are sure, be appreciated. The book consists of two parts, the first dealing with the most important and modern methods of technique, the second with diagnosis and pathology. So far as it goes, it is good, but it is perhaps just a little short. It is illustrated by some seventy or more micro-photographs which are admirably reproduced.

#### New Appliances.

##### IMPROVED HAGEDORN'S NEEDLE HOLDER.

MR. CECIL H. LEAF, M.B. Cantab., F.R.C.S. Eng., sends us the following description of an improved needle holder:—

One drawback, he remarks, which may be urged against Hagedorn's Needle Holder is that a somewhat uncomfortable movement of the little finger is necessary to unlock it. I have therefore requested Messrs. Arnold and Sons, of West Smithfield, to construct a Hagedorn with a Macphail's catch. This renders the unlocking a comfortable process. The holder as thus modified is shown in the accompanying illustration.

#### Laboratory Notes.

WE have received from Messrs. Burroughs, Wellcome samples of various preparations of obvious value to the medical profession. We may especially mention "Soloid" of Ferric Chloride, gr. 10 (0.648 gm.). The advantages of this preparation are that it avoids the need of carrying about a solution of ferric chloride. Each product represents the amount of ferric chloride contained in 40 minims of solution of ferric chloride,

(a) "Orthmann's Handbook of Gynæcological Pathology for Practitioners and Students." Translated by C. Hubert Roberts, M.D., F.R.C.S., M.B.C.P. Physician to the Samaritan Hospital, London. Physician to the Out Patients, Queen Charlotte's Lying-in Hospital, London, &c., &c., assisted by Max L. Trechmann, F.R.C.S., London: John Bale, Son, and Danielsson, Ltd., 1904. Pp. XV. and 17.

B. P., and one, dissolved in a sufficient quantity of water to produce 40 minims, forms a solution equivalent to the official strength. By varying the quantity of water, this strength may be increased or diminished according to circumstances.

Another convenient preparation is the "Tabloid" Ferric Chloride,  $\pi$  10 (0.592 c.c.). This will be found a convenient means of administering ferric chloride, especially to patients requiring a regular course of treatment.

For the preparation of antiseptic solutions "Soloid" Mercuric Potassium Iodide, gr. 4.37 (0.283 gm.), will be found most convenient. One dissolved in ten ounces of water forms a solution of 1 in 1,000 (frequently known as mercury binioidide solution). The colour of "Soloid" Mercuric Potassium Iodide is due to a harmless ingredient added as a safeguard against errors.

The list of "Soloid" preparations includes:— "Soloid" Mercuric Potassium Iodide, gr. 1.75 (0.113 gm.), issued in tubes of twenty-five, and bottles of 100; "Soloid" Mercuric Potassium Iodide, gr. 4.37 (0.283 gm.), issued in bottles of twenty-five and 100; and "Soloid" Mercuric Potassium Iodide, gr. 8.75 (0.567 gm.), issued in bottles of twenty-five and 100.

## Medical News.

### Vaccination Frauds.

At the Old Bailey last week, Hugh Stanley Revell, 35, surgeon, who had pleaded guilty to having, whilst medical officer under the Guardians of the Wandsworth and Clapham Union, falsified certificates of vaccination and thereby defrauded the guardians of considerable sums of money, was brought up for sentence. The Recorder sentenced him to seven weeks' imprisonment, which entitled him, as he had been in custody for three months, to be at once discharged.

### Value of an Eye.

At the Congress of Ophthalmologists, which was opened at Lucerne last week, there was a discussion of the question as to what value should be placed upon an eye, injured or lost, with a view to fixing an indemnity. A number of papers on the subject, including one by Dr. Wurdemann (Milwaukee), were read. A resolution, proposed by Dr. Fuchs (Vienna), was adopted declaring that the congress had no power to draw up a definite table of damages applicable in all countries, as the laws on the subject were everywhere different. With regard to the question of the determination of the power of vision, the congress decided to elect national committees for the purpose of collecting material to be submitted to the next congress.

### The Inspection of City Restaurants.

THE Public Health Department of the London City Corporation has issued its first certificate of cleanliness under a new scheme for the attainment of cleanliness in the kitchens of restaurants and above-ground bake-houses within the City area. Dr. Collingridge, the medical officer of health for the City, states in a report that repeated representations have been made by owners and occupiers, who, having been called upon to carry out repairs and improvements, felt strongly that, as some recompense for the outlay, they should be in a position to exhibit a certificate that their premises were in a satisfactory sanitary condition. A standard of requirements has been drawn up, and further certificates will be issued after the Court of Common Council reassembles on September 22nd. With regard to restaurant kitchens, one of the suggestions is that each kitchen should have a *minimum* height of 8 ft., a *minimum* cubic capacity of 1,500 ft., except in special circumstances, and not less than 400 cubic feet per head for each person employed therein.

### The Medical Profession.

THE Winter Session, 1904-05 will commence on October 1st. The entrance examination for the Con-joint Diploma, medicine, surgery, and midwifery of the Royal College of Physicians and Surgeons, Dublin, will be held on Monday, September 26th. Entrance-form and Medical Student's Guide can be had at the Royal College of Surgeons, Stephen's Green, Dublin.

### Food Adulteration in London.

THE Local Government Board, in view of the fact that from 1894 to 1903, inclusive, only 143 samples of food—mainly milk—out of a total of 5,792 samples analysed by Dr. A. Wynter Blyth, Marylebone's public analyst, were reported to be adulterated, or 2.4 per cent. against a percentage of 11.7 throughout the Metropolis, asked how this disparity was accounted for. The Board also pointed out that, although Dr. Blyth stated before a departmental committee that he met with many samples of milk treated with borax or boracic acid, yet there was no reference in his reports during the past five years to the presence of preservatives in the milk and butter examined by him. Dr. Blyth, who is supported in his answer by the Marylebone Borough Council, has replied that the reason of Marylebone's comparative freedom from adulteration is that a systematic sampling of offenders on the "black list" has driven them further afield. He adds: "A few years ago Marylebone took more samples in proportion to its population than any other London borough, and it is reaping the advantage of its activity." Concerning the preservation of milk by means of borax, he says that, unless a standard is fixed, seeing the wide difference of professional opinion on the matter, he is unable to certify as adulterated a boraxed milk or cream, save the quantity is excessive."

### X-Rays in Blood Diseases.

DR. BOZZOLI, director of clinical medicine at the Turin University, has informed the Academy of Medicine that experiments he has made have shown that the X-rays have remarkable efficacy in some serious diseases of the blood. He says that he has cured by this means a supposedly incurable case of leucæmia.—*Electricity*.

### Disinfection of Books.

THE authorities of the various public libraries in the city of Berlin have for some time past occupied themselves with the question of disinfecting the books. To this end a number of books which had been in use in the libraries for more than two years were examined by medical experts, who declared that they contained tubercle bacilli, also dangerous germs, which were conveyed to the books by persons suffering from consumption turning the leaves over with their saliva-covered fingers.

At the meeting of the Committee of Management of the Clare County Infirmary, held on Monday, the 5th inst., the committee, through their chairman, congratulated Dr. Faris, surgeon to the infirmary, on his restoration to health, and said: "The governors were very pleased with the manner in which he always discharged his duty."

At the meeting of the Rathkeale Board of Guardians, held on Wednesday, the 7th instant, a letter was read from the I. L. G. Board refusing to sanction the payment of an operation fee to Dr. Thomas Hayes. They based their refusal on the ground that Dr. Hayes was the medical officer of the workhouse, although he was on his holidays on the occasion. The facts of the case are: Dr. Hayes, though on his holidays, was still at home, when he was requisitioned by his medical substitute to perform an urgent operation on an accident case. He immediately complied with the call and is now refused his legitimate fee. Suppose he had gone one hundred miles from home and been similarly requisitioned, would he not be entitled to charge? Does distance make the difference?"

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

### A POPULAR FALLACY.

A COMMON popular error is that a doctor is compelled to go to a case whenever he is sent for—as though he were a public official subsidised out of the public funds. Indeed, this was the idea of a jurymen at the inquest upon a recent Manchester case, to which the doctor had declined to go.

"What are you paid for, I should like to know?" he indignantly asked the doctor.

"Do you pay me?" the latter inquired.

"Aren't you paid out of the rates?" then asked the sapient jurymen.

M.R.C.P.—The reduction in space given to your Institution in our Students' Number was unavoidable.

FIFTH YEAR.—The next examination of the Medico-Psychological Society will be held on November 7th. You will find the necessary particulars on reference to our advertising columns.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 21st.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chelms Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical.)

THURSDAY, SEPTEMBER 22nd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chelms Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY, SEPTEMBER 23rd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chelms Street, W.C.).—4 p.m. Dr. D. Grant: Clinique. (Ear.)

## Vacancies.

Birkenhead Borough Hospital.—Junior Resident House Surgeon. Salary £80 per annum. Applications to the Honorary Secretary.

Horton Infirmary, Banbury.—House Surgeon. Salary £80 per annum, with board and residence in the Infirmary. Applications to the Honorary Secretary, 21 Marlborough Road, Banbury.

Halifax Union Poor-law Hospital.—Resident Medical Officer. Salary £120 per annum, with apartments, rations, and washing. Applications to Arthur T. Longbottom, 4 Carlton Street, Halifax.

Liverpool City Infectious Diseases Hospitals.—Assistant Resident Medical Officer. Salary £120 per annum, with board, washing, and lodging at the hospital. Applications to the Chairman of the Port Sanitary and Hospitals Committee, c/o Town Clerk, Municipal Office, Liverpool.

West Riding of the County of York—Stories Hall Asylum, Kirkburton, near Huddersfield.—Assistant Medical Officer. Salary £140 per annum, with furnished rooms, board, attendance, and washing. Applications to the Medical Superintendent.

Manchester Corporation—Monnal Fever Hospital.—Fourth Medical Assistant.—Salary £100 per annum, with board, lodging, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Ancoats Hospital, Manchester.—Resident House Physician. Salary £80 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

Kidderminster Infirmary and Children's Hospital.—House Surgeon. Salary £120 per annum, with rooms in the Infirmary and attendance. Applications should be addressed to the Secretary on or before September 23rd. Canvassing not allowed.

Croydon Union.—Resident Assistant Medical Superintendent and Dispenser at the Infirmary, Mayday Road, Croydon. Salary £180 per annum, with furnished apartments, rations as per scale, and washing. Applications to Harry List Clerk to the Guardians, Union Offices, Mayday Road, Thornton Heath.

Newcastle-upon-Tyne City Hospital for Infectious Diseases.—Resident Medical Officer. Salary £100 per annum, with board, lodging, &c. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

National Maternity Hospital, Dublin.—Intern Assistant Master. Salary £50 per annum. Immediate application to Secretary, Holles Street. (See advt.)

## Appointments.

HAYNE, LOUIS B., M.D., B.C. Cantab., Honorary Medical Officer to Out-patients at the Harrogate Infirmary.

HUST, A. W. D. L.R.C.P.Lond., M.B.C.S.Eng., Surgeon to the Loyal Crown Lodge of Oddfellows at Chagford (Devon).

KIRTON, MARTIN A., M.B.C.S.Eng., L.R.C.P.Lond., Public Vaccinator for the No. 2 District by the Devonport Board of Guardians.

LEVICK, G. K., M.B.Lond., Medical Officer of Health to the Havant Urban District Council.

MOSEY, SYDNEY G., M.B.Oxon., Medical Officer of Health of South Shields.

RYAN, RICHARD P., F.R.C.S.Irel., Public Vaccinator to the First District by the Devonport Board of Guardians.

SAYER, THOMAS, M.R.C.S.Eng., L.R.C.P.Lond., Medical Officer and Public Vaccinator for the Kirklington District of the Bedale Union and for the Pickhill District of the Thirsk Union.

## Births.

BLOMFIELD.—On Sept. 12th, at Horsefair, Pontefract, Yorks, the wife of George Wills Blomfield, M.D., of a son.

ECCLES.—On September 18th, at 124 Harley Street, London, the wife of W. McAdam Eccles, M.S., F.R.C.S., of a son.

LAWLESS.—On Saturday, September 10th, the wife of George R. Lawless, F.R.C.S.I., Medical Superintendent, Armagh District Asylum, of a daughter.

WEBSTER.—On Aug. 28th, at Toorak, Melbourne, Australia, the wife of Dr. Percy S. Webster, of a son.

WHIRLAN.—On September 12th, at 28 Synnott Place, Dublin, the wife of James A. Whelan, L.R.C.S.I., of a son.

## Marriages.

COAD—YUILL.—On September 17th, at St. Mary Abbott's Church Kensington, London, Stanley Allan Coad, M.B.C.S., L.R.C.P., 7 Elgin Avenue, London, W., third son of Thomas Coad, late of the Horse Guards, Whitehall, to Sarah youngest daughter of the late John Yuill Hill side, Partick Hill Glasgow.

TURNER—HAMILTON.—On September 14th, at the Parish Church, Tavistock, Devon, William Turner, M.S. (London), F.R.C.S., of 53 Queen Anne Street, Cavendish Square, London, to Lily, only daughter of John Kerr Hamilton, of St. Bimons's, Tavistock.

## Deaths.

BENHAM.—On September 14th, Harry Arthur Benham, M.D., Medical Superintendent of the Bristol City and County Asylum, aged 49.

BIDDLE.—On September 18th, at Charlton Lodge Kingston-on-Thames, Frances Eliza Lydia, the beloved wife of Daniel Biddle, M.B.C.S.Eng., and L.S.A.Lond.

HARDY.—On September 16th, at West Haddon, Euby George Hardy, M.B.C.S., in his 85th year.

HUTCHINSON.—On September 15th at his residence, Ford, Branksome Park, Bournemouth, Samuel John Hutchinson, M.B.C.S., L.D.S. Lond., of 64 Brook Street, Grosvenor Square, London, aged 58.

JAMESON.—On September 13th, at Newlands, Eltham, Surrey, General James Jameson, C.B., &c., late Director-General Army Medical Service, aged 67.

## OPERATIONS.—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (2.30 a.m.), Gt. ## Original Communications.

### THE HOSPITAL ISOLATION OF SCARLET FEVER.

By A. MEARNS FRASER, M.D., C.M., D.P.H.  
Camb., &c.,

Medical Officer of Health for Portsmouth.

No branch of sanitation is receiving more attention at the present time than that which comprises the prevention of infectious diseases by aggregation of the cases in a so-called isolation hospital. It is therefore interesting to remember that the establishment of isolation hospitals all over the kingdom was not the result of the careful observation of the successful working of a hospital in the prevention of the disease; the now almost universal adoption of isolation hospitals is based on the idea that it must inevitably be beneficial to remove every case of infectious disease from the house in which it exists to a place where it can be kept by itself away from all other members of the community. Now, this is a common-sense view that appealed to all, and one is quite prepared for the feverish anxiety of some medical officers of health to have every infectious case in their district removed at once to the hospital, and one can quite appreciate the action of most medical officers of health in regarding the isolation hospital as their principal weapon for fighting infectious disease. It was, and is now, though possibly to a less extent, usual, if infectious disease had not been very prevalent in a district, to attribute this to the provision of an isolation hospital, and in annual reports on such districts congratulations were offered to the sanitary authority on their foresight in providing such isolation hospital accommodation; on the other hand, if infectious disease had been more prevalent than usual one often noticed regrets expressed that the isolation hospital accommodation had proved insufficient to cope with the outbreak; the disease in question had spread, and sanitary authorities were urged to make further provision in the future.

During the last year or two, however, in the minds of a number of medical officers of health there has arisen considerable doubt as to whether the benefit of isolation hospitals is really so great as has generally been supposed; some, indeed, having got past the stage of doubt, insist that at any rate as regards the prevention of scarlet fever isolation hospitals are of little use. The reasons that have brought about this change of thought are not far to seek.

The isolation of scarlet fever cases in hospitals

has been practised in many large towns for about twenty years: this is a long enough period for the system to be effectually tried, and in those places at which it has been most persistently carried out there should surely be some diminution in the scarlet fever prevalence. This, however, is not the case: towns isolating a large percentage of their scarlet fever cases can show no appreciable improvement in this respect over other towns which have isolated few or none; curiously enough, too, some towns which have isolated very few of their cases show a greater diminution than those which have practised extensive isolation. The case of Birmingham has been quoted; this city, which is second only to Huddersfield in the extent of isolation practised (84 per cent. of the cases of scarlet fever being isolated during the ten years 1890-1899), actually had an attack-rate in 1902 of 9 per 1,000 population, an attack-rate larger than in any previous year since 1890 and higher than in any other large town in the kingdom in that year. Indeed, a return of the scarlet fever "attack-rates" existing in the various towns compared with the amount of hospital isolation practised affords very instructive reading, and anyone interested in the question cannot do better than obtain a copy of Dr. Killick Millard's paper on the subject. (a)

To what, then, can this non-success of the isolation hospital in the control of scarlet fever be attributed, and what are the reasons which have withheld the results so confidently anticipated by sanitarians at the inception of the isolation hospital? I believe they may be found in the fact that the originators of the system overlooked some of the difficulties in the way of securing complete hospital isolation. Under the Infectious Diseases (Notification) Act it was doubtless anticipated that in the first place every case of scarlet fever occurring in a district would be promptly notified to the medical officer of health, and, if incapable of being isolated at home, would be promptly removed to the isolation hospital; and, secondly, it was believed that once admitted to hospital it would remain there till free from all infection, so that on its discharge there need be no fear of its again spreading the disease.

In practice, however, this ideal has never been attained. In the first place it is well known that in every town a number of cases of scarlet fever occur which are of so slight a character that no medical man is called in and they are only discovered, if at all, through investigating the source of other and possibly more severe cases which have arisen from

(a) "The Influence of Hospital Isolation in Scarlet Fever." By C. Killick Millard, M.D., D.Sc. London: Ebbman, Ltd.

those originally unrecognised. To these must be added cases which are concealed, either because the parents are afraid of their children being compelled to go to hospital, or because it is feared that the knowledge of the existence of a case of scarlet fever in the house may interfere with the work of the wage-earners of the household. Here, then, is one reason for the want of success of the isolation hospital; there is, however, an even more important factor.

I have said that the object of the isolation hospital is to retain the case of scarlet fever until it can safely be returned to the community without fear of again spreading the disease. It must be obvious that this is a fundamental principle of the system, the complete attainment of which is an absolute essential for the success of the isolation hospital, yet again, in actual practice this ideal has never been attained. I believe there is no hospital superintendent in the kingdom who would be prepared to guarantee that any particular individual, on his or her discharge from the hospital, was actually free from infection, and incapable of again spreading the disease on mixing with other susceptible members of the community. Indeed, "return" cases are so common that paper after paper has been written, and innumerable discussions have taken place to find out how it was that scarlet fever should still be spread by patients who, to all appearances, were discharged from hospitals perfectly free from infection. Further, it is now the practice in most towns to issue printed notices that the patient should on his discharge from hospital be kept away from school and other children for periods varying from a week to a month. In spite of these precautions, however, return cases persist with a disheartening regularity.

The above are, I believe, the two chief explanations why isolation hospitals do not, and, moreover, are not likely, so far as we can see, to control the prevalence of scarlet fever in a town. And if it cannot be shown that isolation hospitals control the disease, there at once disappears the chief *raison d'être* for their existence.

I must mention, however, another argument that is often urged in favour of hospitals—namely, the actual benefit to the patient from the superior nursing he will in most cases obtain in hospital, compared with that provided at home. Here, again, the experience of past years has not supported this contention, for the number of cases of adenitis, rhinorrhœa, and otorrhœa that occur periodically in every scarlet fever ward, to say nothing of others which, admitted with scarlet fever, contract in addition such diseases as measles, whooping-cough, diphtheria, and chicken-pox, are so numerous as, in the opinion of many, to counteract any extra advantage that may be derived from trained hospital nursing.

There is yet another side of the question that must be considered, and one that I have in the past laid considerable stress upon, namely, the financial aspect.

I believe that in the departments of most medical officers of health one of the principal, if not actually the largest item of expenditure is the isolation hospital. Now scarlet fever, although, as known at present, an exceptionally mild disease, yet is so prevalent that 75 per cent., and often more, of the accommodation at isolation hospitals in large towns is nominally taken up by this disease alone. Millions have been spent on the erection of isolation hospitals and hundreds of thousands are annually

spent on their maintenance. Now as by far the larger part of the cost of the erection and maintenance of hospitals is undoubtedly incurred through an attempt to control scarlet fever, the reflection must occur whether sufficient justification exists for the expenditure of such large sums of money on a disease that, with the exception only of chicken-pox, causes a slighter mortality than any of the common infectious diseases. If the hospitals were really controlling the disease, and if year after year, as isolation methods improved, a corresponding diminution in its prevalence were noticeable, then possibly some excuse for the expenditure might, in spite of the mildness of the disease, be found. But as the facts exist at present, with the annual expenditure on isolation hospitals growing larger and larger, and at the same time scarlet fever, if not becoming more prevalent, at least not showing any diminution, then it does indeed seem that the time has arrived when an official inquiry as to the advisability of modifying or improving the present system should be instituted.

If it should be found that, owing to our inability to define the length of the infectivity of the disease, not much improvement in the present method can be hoped for, then let the money devoted to scarlet fever be spent in other directions, such as the betterment of the houses of the working classes. Money spent in this latter direction cannot fail to give some definite beneficial return, and it is to my mind a question whether, if the same money which has been expended in the past on the isolation of scarlet fever had been devoted to clearing away slum property, we should have had far better results to show, not only in the improved dwellings of the working classes, but also indirectly in that diminution of infectious disease which always results from the improvement of the homes of the poor. One word in conclusion: in the above remarks and in previous writings on the subject of isolation hospitals, I have limited myself entirely to their connection with scarlet fever, and nothing that I have said applies to enteric fever, small-pox, or diphtheria. Moreover, I am not advocating the total abolition of the hospital isolation of scarlet fever; under existing legal enactments it is difficult to see how sanitary authorities can avoid providing accommodation for a certain small percentage of the cases that occur; inasmuch as a dairyman, or a tailor and a few others are legally prevented from pursuing their usual employment whilst scarlet fever is present in their houses, it is only right that provision should be made for removing and treating these cases elsewhere. What I do contend, however, is that it is quite time a thorough investigation was held to ascertain if the wholesale isolation of the mild cases of scarlet fever that is practised at present is worth the large sums of money expended upon it, and incidentally to have an authoritative opinion as to whether there are not good reasons for supposing that the money now spent on the hospital isolation of scarlet fever cannot be more profitably employed in other directions.

In an inquiry of this nature the evidence to be sifted will be considerable, and it is essential that it should be conducted by men of weight and standing. Personally, I should like to see it the subject of a Royal Commission; moreover, as suggested by Dr. Millard, laymen might with advantage be on such a board of inquiry; the question is largely one of finance, and it would be of

great value to have the opinion of men of experience in local government administration, men who, leaving the purely medical aspect to their medical *confères*, would be able to pronounce a judgment as to whether the results obtained from the hospital isolation of scarlet fever as at present practised afforded an adequate return to sanitary authorities for the expenditure involved.

### SCIATICA. (a)

By J. E. HARBURN, L.R.C.P., L.R.C.S.Ed.,  
Buxton.

THE subject which I desire to briefly draw your attention to is one of considerable interest on account of the intractable nature of the complaint, and also by reason of the difficulty which is often experienced in affording relief. This is evidenced by the numerous remedies which have at various times been suggested for its treatment.

Judging from the large and increasing number of cases which are sent to health resorts year by year for special treatment, it would seem that sciatica in many instances tends to assume a chronic course, and exerts a most debilitating and depressing effect on the health of those who suffer from it. During the past seven years over 400 cases have been treated in the practice which is conducted by my colleague, Dr. Armstrong, and myself at Buxton; and it is from consideration of the notes of these cases that I have drawn the observations which I venture to bring before you to-day.

The term "sciatica" is somewhat loosely used to describe all painful conditions of the sciatic nerve or its branches, but experience shows that the following classification is desirable:—

- (a) Sciatic neuralgia.
- (b) Sciatic perineuritis.
- (c) Sciatic neuritis.

(a) Sciatic neuralgia is frequently of a very temporary character and may be simply functional, probably showing no change whatever in the sheath of the nerve. When the general health of the patient is low, however, it is often of considerable duration. The pain may be intermittent, and there is usually tenderness at two or three points of the nerve. It often occurs in patients who have neuralgia in other parts.

(b) Sciatic perineuritis sometimes precedes or follows neuritis, and in these cases we have to deal with the symptoms of sciatic neuralgia and sciatic neuritis. There is generally tenderness along the whole of the upper third of the nerve, and the surface temperature of the limb may be reduced. The patellar reflex may be intensified.

(c) Sciatic neuritis is infinitely the most serious and intractable form of the disease, and a large proportion of the most refractory cases come under this heading. There is great tenderness not only of the nerve itself, but over the surrounding parts. The temperature of the limb is always reduced; there is tingling and numbness and muscular atrophy in the later stages. The patellar reflex is sometimes lost, and cases of this variety have been mistaken for locomotor ataxia.

Accurate differentiation is of the utmost importance both as regards prognosis and treatment, for while cases of the first group can, as a rule, be speedily cured, those in the second are more troublesome, and in the third the most refractory

of all. As I hope to show later, the treatment indicated varies greatly. Methods which are of service in Class A are absolutely harmful in Classes B and C.

The causes of sciatica are in some cases difficult to trace. In the great majority of cases, however, there is a gouty or rheumatic taint present, and in a striking number of instances the patients had been subjected to great worry and over-pressure, which had lowered the nerve tone, probably inducing defective metabolism and tardy excretion of body waste. A large number of these cases occurred in over-worked business and professional men.

The exciting causes of sciatica are cold, damp, and traumatism. Possible pressure within the pelvis from constipation, uterine displacements, tumours and aneurysms must not be lost sight of. Neuritis is often caused by the action of such poisons as lead, arsenic, and alcohol, and it should be remembered that the subjects of glycosuria and diabetes are very liable to this affection of the nerve. In not a few cases sciatic neuritis occurs as a sequel to influenza.

*Treatment: Acute Sciatica.*—Whatever variety of the disease is present, in the acute stage rest is absolutely essential. In many instances a well-padded splint extending from the spine to the foot is of great service. Dry heat applied by means of the Tallerman apparatus, or of its offshoots, the Greville or Dowsing methods, or if these are not available, by the application of indiarubber hot-water bottles, will be found most effective. With regard to drugs, no combination has, in our experience, been so effective as the following:—Aspirin, 6 grains; phenacetin, 5 grains; salicylate of quinine, 2 grains; and codeinæ,  $\frac{1}{4}$  to  $\frac{1}{2}$  grain.

The bowels should be well cleared with small doses of calomel followed by salines. In those cases in which the pain is not relieved an occasional injection of morphia with atropine may be necessary, but this is a remedy which should be used with great caution and not too frequently repeated, as it tends to interfere with the excretion of body waste, and may also lead to the establishment of the morphia habit.

*Subacute Sciatica.*—It is in this stage of the trouble that the various spas become of service. In Buxton we have found nothing so successful as the half combined bath. The patient sits in a vapour bath which comes up to the waist line only; this, while not so exhausting as the full vapour bath, allows a higher temperature to be borne by the affected parts. Thus a temperature up to 115° F. can be tolerated with advantage for from ten to fifteen minutes. At the end of this time the patient sits in a bath of the Buxton thermal water, heated to a temperature of 95° for eight minutes, and during the last three minutes a hot under-current douche at 102° to 110° is applied to the affected limb.

In this stage also electricity in various forms is used with excellent results. The sinusoidal electric water bath (200 alternations per second), or the high frequency currents of D'Arsonval, are the most useful, as they have a distinctly anæsthetic effect upon the nerve, whilst improving its nutrition. Acupuncture has often been found beneficial at this stage, as has also the application of menthol plaster or a blister over the head of the affected nerve, or the use of the thermo-cautery. The administration of fairly large doses (10 to 15 grains) of iodide of potassium three times a day

for three or four days is sometimes beneficial, and in some instances the combination of this with arsenic has been of great service.

*Chronic Sciatica.*—In the treatment of the chronic forms of sciatica it is essential that distinction should, as far as possible, be made between true neuritis and other forms of this complaint. Where neuritis is not present the Aix massage bath with the douche applied to the painful part is of great value, as are also dry and electric massage, followed by gentle stretching of the nerve in cases where adhesions are present. The Buxton swimming bath at the natural temperature of 82° F. is one of the most valuable remedies at our disposal.

In true neuritis, however, massage is, as a rule, most harmful, and nerve-stretching is quite contra-indicated. The warm immersion bath with hot under-water douche or the natural swimming bath will greatly help these patients; and electricity in the form of the constant current ascending and descending over the affected nerve, or the constant current bath, is of much service.

The affected limb should be kept warm by the wearing of double socks and pants. Dr. Farquhar, of Marlborough, speaks very highly of the injection of one-third grain of pilocarpin nitrate on alternate days for two or three weeks, except in cases where there is organic mischief. In some very obstinate cases of sciatica the injection of osmic acid has been used with success, but it is a drastic and uncertain remedy.

If the pain is perpetuated by adhesions which gentle nerve-stretching does not break down, forcible stretching under anæsthesia may be resorted to.

In some cases where all else has failed the nerve has been cut down on and forcibly stretched, and in two cases it was found that the sheath and nerve were so intimately connected that the former had to be dissected off. Dr. Crawford Renton, of Glasgow, has published a series of remarkable cases in which this condition was found.

## PROLONGED LACTEAL SECRETION AS A CAUSE OF CONSTITUTIONAL DEBILITY(a)

By DR. L. CHEINISSE,

Ex-Interne of the Montpellier Hospitals, Laureat of the Faculty of Medicine.

THE mammary gland of the female is intimately associated, physiologically, with the genital function, and closely resembles that gland in the male, from which, indeed, it only begins to differ at the onset of puberty. Essentially an intermittent function, the mechanism of lacteal secretion is usually set up by reflex stimulation such as the presence of a foetus in the uterus or suction applied to the nipples by the infant. These conditions, however, by no means comprise the whole of the natural history of the mammary gland, for there are many other exciting causes capable of starting or maintaining the secretion. Though rather rare than otherwise, instances of the kind are frequent enough for them to have been recognised and classified. Some twenty years ago, Dr. R. Duval went into the subject thoroughly and described five categories of non-puerperal lacteal secretion: (1) Cases in which the secretion is prompted by the menstrual function; (2) cases in which the stimulus comes from a tumour of the breast; (3) cases in which there is secretion of milk in connection with some utero-ovarian affection; (4) cases in which it is set up

by mechanical or psychical stimulation unassociated with any structural changes in organs; and (5) instances of persistent lacteal secretion after the menopause.

I recently had under observation a patient who exhibited a further anomaly of the lacteal function, one which possesses something more than a pathological interest, since it may determine consequences very detrimental to the health and comfort of the victim. The patient was a young primipara, who, in consequence of the inadequacy of her secretion of milk was constrained to supplement the supply by a proportion of cow's milk. Five months later she was obliged to absent herself for some weeks, and the child had therefore to be weaned at short notice. Two days later the breasts had become swollen and painful, and relief was obtained by emptying them by aspirating the milk. She continued this practice for a fortnight several times daily to begin with, and subsequently, as the quantity of milk diminished, less frequently. The gland, however, went on secreting, though not in any large amount, but milk flowed away when even slight pressure was applied to the breast, and during the night enough escaped to wet the front of the night-dress. The secretion increased in amount on the slightest fatigue, even after moderate walking. The inconvenience did not go beyond this, so the lady did not consider it necessary to seek advice on the subject.

She was living at this time under very healthy conditions, but she noticed that she was losing weight and had become subject to attacks of palpitation. The family physician, to whom she applied without mentioning anything about the persistence of the secretion, recommended a change of air and the ordinary remedies for anæmia. This treatment failed to do her any good, and as she continued to lose flesh and strength she ultimately consulted me. I, too, was struck by the manifest anæmia, and, for a time, I was unable to discover any plausible explanation of its occurrence. The heart and lungs appeared to be normal, and the abdominal organs revealed no evidence of disease. Menstruation, which had recurred soon after the infant had been weaned, had since been normal in date and amount.

This was as far as I had got with my investigation when one day, while auscultating the heart, I noticed that the pressure of the stethoscope brought some drops of milk from the left nipple. On squeezing the mamma more milk came away, and on repeating the experience on the other side the same effect was produced. Naturally, my first thought was that the lady was again pregnant, but apart from the fact that she had menstruated regularly I was unable to discover any other sign to confirm my assumption. Moreover, on questioning her, I found that, as a matter of fact, the secretion had never ceased since her child was weaned, that is to say, twenty-six months previously. She said she did not attribute any importance to the presence of milk in the breast, and from motives of modesty had abstained from mentioning the matter. It at once occurred to me that there might be a close relationship between the persistence of this secretion and the disturbances of nutrition which the patient presented, and which had resisted the usual stomachic treatment. Before making up my mind I thought it desirable to ascertain the exact nature of the secretion. Under the microscope I found colostrum corpuscles, true milk globules, and a few epithelial cells undergoing disintegration. These figured elements were isolated and disassociated—a circumstance which, according to Palazzi, justifies the presumption that the secretion is not the outcome of a fresh pregnancy, but is due to persistence of the function long after the period of lactation.

With these data before me and with the object of arresting the lacteal secretion, I prescribed ten-grain doses of antipyrine three times daily, in cachet. In the course of a few days the patient found that milk could no longer be squeezed out of the breasts. It may be simple coincidence, but the fact remains that from this date the patient gradually improved in health.

(a) See *La Semaine Médicale*, July 13th, 1904.

and soon ceased to experience any symptoms, although no other treatment was resorted to; in fact, within a few weeks she had quite recovered her normal standard of health.

This case is interesting not only as an example of remarkable persistence of the lacteal secretion, but also, and more particularly, on account of the influence which this abnormality exerted on the general health. Exceptional as the occurrence may appear at first sight, it is in reality by no means unique. Putting aside for the moment the question of the impairment of health caused by this anomalous secretion, I should like to discuss the persistence itself. Under ordinary circumstances the hypertrophy and secretory activity of the gland are limited to the period of lactation, and when this has come to an end, though the cells continue to secrete for the first few days after the weaning of the child, the alveolæ then begin slowly to retract. Large numbers of fat cells are detached from the membrane and undergo transformation into a residue which is ultimately in great part absorbed. The gland recedes and remains quiescent until another pregnancy summons it from the reserve and starts it again on active service. That is the general law, and although it admits of certain exceptions, these departures from the normal have not, so far, received sufficient attention. I note, indeed, that in three recent works on the lacteal function the only aberration mentioned is that in some countries, Hungary for instance, women of the labouring classes continue to suckle their infants till the age of three years, and even more. Observations of this kind have obviously nothing in common with the subject under consideration, which concerns the persistence of the lacteal function long after the period of lactation or even in the absence of lactation, an instance of which is recorded by Tceitline in a woman in whom the secretion of milk was maintained for five years, although she had never given her infant the breast. This case, however, is not on all fours with my own, in that the patient was the subject of chronic metritis.

But, leaving on one side cases in which the milk secretion is under the empire of some affection of the uterus or ovaries, we must admit that there are cases in which weaning the child does not put a stop to the secretion. Dr. Opitz, protesting against the distinction usually inculcated between colostrum and milk, according as the fluid does or does not contain colostrum corpuscles, says: "We meet with cases in which there is a copious secretion of milk a year or more after the normal period of lactation has terminated—a secretion which contains colostrum corpuscles, but is microscopically indistinguishable from milk." Palazzi, on the other hand, refers to three women with persistent secretion of milk, who had weaned their infants respectively seven, seventeen, and thirty-two months previously.

Not only may the secretion of milk continue for long periods of time, but it may be very abundant, amounting, it may be, to genuine galactorrhœa. Instances of this kind are on record in medical literature, and in the Transactions of medical societies, which, although not referred to in works specially devoted to anomalies of lactation, are nevertheless worthy of attention.

Moir reports the case of a woman in whom, although she had never brought up any of her children at the breast, the secretion invariably persisted until the third month of the next pregnancy. After the birth of her second child, the function remained active for eighteen months, after the third for two years, after the fourth for twenty-five months, and after the fifth for twenty-four months, when she had a miscarriage, since which she has not again been pregnant. Kneeland publishes notes of a case in which a woman, æt. 35, who had given birth to a child five years previously, still continued to secrete milk, though she gave up suckling the child at the end of two years. Dr. Gibbons brought before the Obstetrical Society of London a case in which both breasts secreted freely for some weeks after delivery, when the milk disappeared from the right breast, soon after which she

weaned the child; but the left breast continued to secrete over half a pint of milk daily for eleven months, when it suddenly ceased on the re-appearance of menstruation.

It is generally recognised that when lactation is prolonged beyond a year or eighteen months it entails more or less serious drawbacks for the mother. Marion Sims, for example, mentions cases of menorrhagia caused by "superlactation," and Sinclair has shown that the sudden termination of unduly prolonged lactation may determine hyperæmia of the utero-ovarian apparatus, and by promoting too pronounced involution of these organs may determine complete or partial prolapse of the uterus. Apart from these complications, we should take cognisance of the constitutional disturbances (exhaustion), and even psychological troubles that have been observed after prolonged lactation.

We now have to ask ourselves whether simple persistence of secretion after the cessation of lactation is capable of bringing about the same troubles. Now it is evident that when the secretion of milk is so copious as to merit the designation of galactorrhœa, this glandular activity entails the same consequences as puerperal galactorrhœa, which, like any other pathological secretion, may modify the tenor of organic exchanges and cause very pronounced denutrition. Dr. Nussbaum states that he has met with several cases in which the mammary glands have persisted in secreting milk for one or two years after weaning, and in such quantity as to be described as galactorrhœa. This was followed by impoverishment of the blood, marked prostration, and loss of control over the emotions, symptoms which he attributes to this persistent and considerable loss of nutrient fluid. In one case the patient, a woman, æt. 37, had suckled her infant until nine months of age, and eighteen months later she still presented bilateral galactorrhœa with consequent exhaustion. A second case was that of a woman, æt. 36, who had had two pregnancies. The child had been weaned at nine months, but the secretion of milk did not cease, and she consulted Dr. Nussbaum a year later, when she presented symptoms suggestive of ulcer of the stomach. In both these cases the administration of laxatives and antipyrine, together with compression of the breasts, had for effect first to reduce, and ultimately to determine, the flow. It should be mentioned that in both cases there were uterine complications, catarrhal endometritis in one and retroflexion of the uterus with catarrh in the second, so it may be that they belong in reality to the group of cases of persistent lacteal secretion dependent upon irritation of the utero-ovarian apparatus. However that may be, the history shows the grave consequences that may be brought about by prolonged and excessive functional activity of the mammae.

Commenting on these two cases, Dr. Nussbaum remarks that he had only been enabled to discover one instance of persistent lacteal secretion (Tceitline), which he had looked upon as unique. As a matter of fact, a number of cases of the kind have been published, and attention had previously been called to the disastrous consequences of this abnormal occurrence. In a work published in 1859, Claude Bernard mentions that instances were met with of women continuing to secrete milk over long periods of time with consequent prostration, and he suggests that diminished activity on the part of the sympathetic nervous system might account for the abnormal function by stimulating excessive circulation. That assumption, he argued, was borne out by the action of electricity, which caused contraction of the blood-vessels by direct stimulation of the gland itself or of the sympathetic nervous system.

These quotations, however, refer only to exhaustion caused by an *exaggeration* of the function, not only in respect of duration but also in respect of quantity. In my case the interesting feature is the evidence that prolonged activity of the secretory apparatus may determine exhaustion even apart from galactorrhœa. Nor do I suppose for a moment that the case is exceptional. In all probability the occurrence is far more

frequent than one might be tempted to suppose, and if it escapes our observation it is simply because the patient does not call the doctor's attention to the abnormal secretion either from motives of mistaken modesty or merely because she does not attach any importance to the fact. In any event, I have satisfied myself that the observation is by no means an isolated phenomenon. Dr. Beltz, for instance, brought before the Medical Society of Rheims the case of a woman who, after her first labour, weaned the infant on the eighth day, yet the secretion persisted for four years without obvious galactorrhœa, since the milk did not flow away of itself. During the menstrual periods, far from diminishing, the flow increased. This patient, he states, presented no very definite symptoms, but she complained of pains in the stomach and the back, debility and general lassitude. He concludes by insisting on the necessity of arresting the flow, which, he opined, was the probable source of the constitutional impairment.

The first lesson to be drawn from these facts is that we must not ridicule the popular idea of the necessity of "getting rid of the milk" when the child is weaned. However absurd may seem the stories that are told of the milk having "gone to the leg," or what not, there may be a substratum of truth in the popular belief. On the other hand, the idea that denutrition can possibly be brought about by persistence of the lacteal secretion is worth bearing in mind, and it should occur to us whenever we have to do with a patient who is suffering from anæmia and emaciation without obvious cause, especially as moderate persistence of the secretion may very well be overlooked by the patient when she applies for advice. Unless the real cause of the constitutional impairment be discovered, we may run through the whole therapeutical arsenal without effecting an improvement.

### Clinical Records.

#### NOTE ON A CASE OF SIMULATED UNILATERAL AMAUROSIS, FOLLOWING AN INJURY RECEIVED UNDER THE WORKMAN'S COMPENSATION ACT.

By THEODORE A. W. OGG, L.R.C.S.Edin., L.R.C.P.Edin., &c.

THE following case occurred in a workman who received a slight injury to the right side of his head during his employment. The injury was of the nature of a bruise and the workman complained of complete loss of sight in the right eye with partial blindness in the left as the result of and following the injury, and as a consequence, inability to follow his employment.

He was wearing at this time a pair of spectacles belonging to someone else of his household. On examination the eyes presented nothing abnormal, and he was then tested with various coloured glasses, through which he was able quite accurately to distinguish the colour of a candle flame, seen, he said, with the left eye.

An opaque disc was then introduced (unknown to him) opposite the left eye and he was then asked the colour he saw, when he again gave the correct colour, stating repeatedly when asked that he saw the flame with his left eye, which, of course, was impossible.

He visited me on the afternoon of the following day and said that his sight was so considerably improved as to be now almost quite well and he would again resume work. I have recorded this case as one of many that are liable to occur under the Workman's Compensation Act, where I have found workmen quite content to remain idle on

half-pay, although a family may depend on their earnings, having no doubt in view the offer of a sum in full settlement of their claim against their employer.

### British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

#### XI.—LYNTON AND LYNMOUTH.

THESE twin villages of North Devon have long been beloved by artists and quiet holiday-makers, but their advantages as desirable health stations have been much overlooked. The peculiar situation, the sheltered glens, the wooded hills, the free exposure to sun and sea, afford conditions which may well prove invaluable in the hygienic management and therapeutic treatment of many delicate persons and not a few actual invalids.

Lynton, which forms the key to Exmoor, is situated on the cliff side 428 feet above the sea, while Lynmouth nestles around the East and West Lynn after their course through rocky and well-wooded gorges. The natural conditions are peculiarly suited to the requirements of the health seeker.

Science and art have also done much to furnish the necessities for hygienic comfort. The water supply is excellent, the drainage good, hotel and lodging-house accommodation is plentiful, and sport in plenty is available for those in a condition to participate.

The thoughtful student and the overworked public man will find the neighbourhood peculiarly rich in interesting features, which afford instruction for mind while at the same time securing recreation for body. (a)

After a careful personal investigation of Lynton and Lynmouth, we are of opinion that it may be recommended as a particularly desirable resting station for busy workers, who, through excessive indulgence in work and worry, feel the fret and fray, the stress and strain of business and profession, and develop conditions which are conveniently summarised as neurasthenia.

The district offers splendid opportunities for graduated hill climbing. Pulmonary diseases and affections benefited by open-air methods should do well during summer months at Lynton.

Persons having heart and other vascular disease would be well advised to select a less hilly station.

Lynton can be reached from Waterloo (L.S.W.R.) in about six and a half hours, the latter twenty miles of the journey being by light railway from Barnstaple. (b)

The vigorous will enjoy the picturesque method of approach by a coach drive of about eighteen miles from Minehead (G.W.R. route).

Visitors may also reach Lynton from Paddington (G.W.R.) *via* Taunton and Barnstaple.

At some seasons of the year, steamers from Bristol stop at Lynmouth, but as there is no pier the landing is difficult, and in rough weather quite unsuited to the invalid.

### France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, September 25th, 1904.  
CORYZA.

ACUTE coryza, popularly called "cold in the head," is, as everyone knows, a very troublesome affection in adults, while in infants it frequently compromises their existence.

Several remedies, both internal and external, have been tried with varying success.

(a) See new volume (No. 27) of "The Homeland Handbooks"—"Lynton, Lynmouth, and the Lorna Doone Country." London: The Homeland Association.

(b) Consult Messrs. Ward, Lock and Co.'s "Pictorial and Descriptive Guide to Lynton, Lynmouth, and North-East Devon."

As internal treatment, M. Ruault recommended benzoate of soda (one drachm for children and twice that amount for adults, in divided doses during the day). This drug arrested the progress of the coryza or abridged its duration. Other agents, such as tincture of belladonna, aconite, or opium, were advised by different authors, but their action was uncertain.

The local means should be preferred. At the first sneeze, inhalation of the vapour of eau de Cologne, so as to produce a sensation of heat in the pituitary membrane, is very beneficial. A few drops of the following solution, on blotting paper and inhaled, also act well:—

R. Phenic acid, 5 ;  
Ammonia liq., 5 ;  
Proof spirit, 1 ;  
Water, 1.

Some rhinologists refuse to prescribe injections of the nares in the acute stage of coryza, contenting themselves with spraying the parts with a warm solution of cocaine at 1-100, or adrenalin 1-1,000. M. Courtade, however, irrigates with a saline or boric acid solution at a very high temperature (118°), which he repeats morning and evening, using a pint at a time. According to him, one or two days suffice to effect a cure if the treatment is begun at the very outset of the attack, the first or second day. If later, the chances of success are diminished; nevertheless the gravity and duration of the malady are always attenuated. M. Courtade prescribes at the same time, internally, salicylate of soda. This treatment would prevent the extension of the inflammation to the pharynx and the bronchi as so frequently happens in certain patients.

In infants, irrigations are impossible; they can be replaced by insufflations of air with an elastic ball, which expel the secretions; instillations of a few drops of a solution of menthol and olive oil (1-150) re-establish the permeability of the nasal fossæ.

#### A NOVEL METHOD OF SUTURING WOUNDS.

A practitioner is called to a case in a hurry without any indication of its nature; arriving at the house he finds himself in presence of a wound that requires to be sutured. He searches in his pocket for his emergency case, and finds he has left it at home. He has come perhaps a long way and does not want to waste time by returning to his house; he is annoyed. Going through his pockets again, he can only discover his little subcutaneous syringe. That is quite sufficient for the purpose, as Dr. Gerest, of St. Etienne, points out, and he will proceed to suture the wound in the following manner:—

Opening the inside lid of the little case, a bundle of silver wires for keeping the needle patent is found. He takes one of these wires and inserts it into the needle, taking care that it does not project beyond the point. He then passes the needle through both edges of the wound; pushing the wire a little beyond the point he holds it while he withdraws the needle. It is thus by this simple method that the suture is through and ready to be twisted. The same operation is done as many times as sutures are needed, and then the edges are drawn together.

The advantage of this simple method over the ordinary operation is that it is much less painful. There is no dragging on the needle loaded with a double thread which is so much dreaded by the patient.

Naturally, the above method can only be applied to simple cutaneous wounds, but do they not form the majority of minor accidents?

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 26th, 1904.

### A MODERN VIEW OF THE ETIOLOGY, PROPHYLAXIS, TREATMENT AND PROGNOSIS OF PULMONARY PHTHISIS.

THIS subject is discussed by Dr. Farnowski in a recent number of the *Prager Med. Wochenschr.* The author believes that pulmonary tuberculosis arises from inactivity and that, therefore, it can be removed by work. He recognises the lymphogenous origin of the disease, the commencement of which lies in the earliest youth. One finds the lymph glands swollen and pleuritic rubbings are often heard. The low power of movement of the apices explain why these parts are the first to be attacked. The prophylaxis consists in the most careful attention to the nose, mouth and fauces, whilst the breathing should be exclusively nasal. All tuberculous subjects with bronchial symptoms should be kept away from children; mothers who are diseased should be forbidden to suckle and nurse their children, and such should be warned against allowing conception to take place. Two symptoms are mentioned as specially characteristic of the early stage: a peculiar, tormenting, burning pain between the shoulder-blades, especially when the body is bent forwards, and a disagreeable sweat odour, often noticed when the clothes are being taken off. The most important therapeutic agent is respiratory gymnastics. As, however, the author does not trust to the exercises being carried out properly, he orders inhalations to be made several times a day of vapour with a medicinal addition. These should act as regards the lung exercise as object lessons from an educational point of view, and also as expectorants. Patients with hæmorrhagic expectoration or pronounced hæmoptysis should not, of course, practise these exercises. In suitable neighbourhoods the terrain treatment is carried out, nasal respiration being indispensable. For inhalation, the prescription following is made use of:—

R. Guaiacoli purissimi.  
Iodipin.

Liquor. sod. sulphiti ana 5 grm.; ft. emulsio.  
S. 1 to 15 drops to be inhaled thrice daily.

The commencing dose was one drop, the length of time and the increase of dose being decided by the condition of patient. The chief aim is the lung exercise, the action of the drug only secondary. Deep nasal inspiration alone had an anticatarrhal influence. With the idea of preventing a fresh invasion of tubercle bacilli, the author orders nasal douching and very thorough cleansing of the teeth with subsequent washing out of the mouth and gargling. Anæmia, one of the most frequent complications of tuberculosis and nervousness, he treats with the same cure. Disturbances of the digestive tract must also be treated; loss of appetite is frequently overcome by solveol, guaiacol, or creosotal. The patient's prospects are improved by careful attention to all the details given. He does not look upon pulmonary tuberculosis as cured when bacilli are no longer to be found in the sputum, but when normal breath sounds are heard again in the chest, when pleuritic rubs and bronchitic symptoms have disappeared, and the lungs have regained their normal elasticity. He looks upon people in the first and second stage of the disease as fit for work, and allows them to work during the time of treatment. He only allows them to announce themselves ill from time to time for purposes

of rest and recruiting from work, by which the treatment is assisted. He looks upon people's curative establishments as without any object, their value lying only in their being places of refuge for the incurable, and as diminishing the chances of infection of others. He also considers treatment in high altitudes as unnecessary, as bronchitis may be prevented by nasal breathing and protection from cold. Finally, he lays the greatest stress on the utmost dexterity and expertness with the stethoscope, whereby the ear becomes familiar with all the sounds of the borderland between the diseased and the normal. He would rather trust the ear than the microscope.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 25th, 1904.

#### FALSE LEGS OF IRON.

At the Naturforscher meeting, Hovorka showed a prosthesis which, he said, had all the advantages of lightness and cheapness that the present age of economy could desire, more particularly in warfare, where so many limbs were mutilated. It was in its simplicity a very light steel tube finished with gauze, which acted as the upholstery for the fitting. He thought the amputating surgeon should work with the instrument-makers in these prostheses, when an operation was performed, as they assisted him to secure by mechanics the greatest utility of the limb, which added greatly to the advantage of the patient's usefulness in after life. There is one small matter in the treatment which should not be omitted. The stump usually atrophies and contracts for some time after the operation. To hasten this action massage should be practised zealously to hasten and harden it for the prosthesis.

#### INCARCERATED HERNIA.

Haberer related the history of a few cases of bowel torsion and incarceration which he had operated on. The first was a hernia associated with purulent peritonitis, which died. The second was torn in replacing the bowel and caused profuse bleeding. The wound was sewn up, the whole cavity washed out, and the bowel returned with a successful issue.

Plucker related a case of hernia which he treated that occurred in the seventh intercostal space after a stab with a sharp instrument which had evidently pierced the diaphragm, allowing the peritoneum and bowel to escape into the chest. Resection of the eighth rib was performed and the whole of the prolapsed bowel replaced after relieving the perforation of the diaphragm, which had strangulated the hernia.

After closing the wound with a few stitches, a tampon was placed over the rupture to hold all in place, but, unhappily, empyema set in and complicated the case, which finally healed up and made an excellent recovery.

Hippel thought that these were very uncertain cases to deal with, as the protrusion of the peritoneum and part of the bowel was no guarantee that other parts of the internal organism were not injured, though the protruding parts were perfectly free and healthy.

Plucker said that a distinction ought to be made between wounding the diaphragm from the abdomen and wounding it from the thorax. In the former case, laparotomy would be the correct method. Again, if the instrument were long and pointed, even when penetrating from the chest, laparotomy should be the operation to follow, but the judgment of the surgeon must be the guide.

Braun then related a few cases of occlusion of the colon from displacement and torsion.

Rhen said that he had only seen one of colon occlusion from torsion and one from displacement of the cæcum, in the case of a girl going to school, and falling on the ice. The great effort to prevent the fall displaced the bowel, and quite closed the lumen. Both cases recovered after the operation.

Hoffmann at this juncture related a peculiar case of laparotomy, which he performed for partial peritonitis, with a supposed purulent abscess according to diagnosis. On opening the abdomen the stomach was distended with five or six litres of brown fluid, resembling that previously vomited. The pylorus was quite free and would permit two fingers to pass. During the operation the patient collapsed. In the post-mortem the pancreas was found necrosed, while all the other organs were healthy.

How this acute dilatation of the stomach occurred was somewhat puzzling. Hoffmann could see nothing to account for it but the sudden loss of atony with a greater amount of distention than usual.

Wohlgemuth related another case of abdominal complexity, where he operated for appendicitis or cryptorchism. Both diagnoses were correctly made. Laparotomy revealed a compromise. Cryptorchism was present with genuine ulceration in the appendix.

#### SURGERY IN JACKSON'S EPILEPSY.

Berge recorded two cases of Jackson's epilepsy on which he operated, the first being six years after the accident to the head. There was a slight impression of the wound still existing on the left parietal bone on the left side, which he raised and found a few sharp spikes underneath, penetrating the grey substance, and along with this a cyst. After removal the fits disappeared, but the paralysis of the right hand and right leg still persisted. The second case was that of a young girl, æt. 13, with a cyst on the floor of the right lateral ventricle. He finally covered the wound with a König flap, which healed perfectly. In a fourth case he could not obtain the same successful result. The epilepsy disappeared all right, but the paralysis still continued after the probable extirpation of the centre, which lies about 1½ centimetre below the surface. After discussing the theory of Jackson's disease, he reviewed the treatment adopted by Jonnescus by extirpating the cervical sympathetic gland on both sides of the neck with the object of reducing the blood pressure in the brain.

#### TO PREVENT URINARY INFECTION.

Goldberg gave the results of his experiments with strepto- and staphylococci, as well as with coli bacilli. This form of treatment was successful in 88 per cent. of the cases where stone was located in the bladder, while eleven were improved. In the case of stricture, 92 per cent. were successful and eight failed; in 78 prostate cases 75 were not infected; in 28 retention cases only three failed; and from 56 infected cases 25 were perfectly healed by the application, and 31 improved.

#### THE SURGERY OF CHRONIC NEPHRITIS.

Stern related the case of an eight-day anuria in which he had operated for calculi in the kidneys, but on reaching the organ he found it to be a case of chronic nephritis on both sides. Two hours after the operation a large quantity of urine was passed, but subsequently the patient died. The post-mortem confirmed the diagnosis of chronic nephritis on both sides.

In another case he tried Edebold's method of decapsulating, but without success. In one of nephralgia he adopted Isreal's method of splitting the enormously distended capsule, which gave immediate relief. The same good result followed the operation in a case of

hæmaturia without any stone as a cause. He is prepared to substantiate Isreal in his opinion of doing good by surgery in these cases.

Rehn advocated great care and caution in the selection of cases for nephrotomy. He had performed the operation in several cases of renal hæmaturia, but lost every one of them. He believed the operation only aggravated hæmorrhage, as the patients always got worse after.

## The Operating Theatres.

### GUY'S HOSPITAL.

**OPERATION FOR CANCER OF THE STOMACH.**—Mr. ARBUTHNOT LANE operated on a woman, æt. 64, who had a tumour in her epigastrium, and suffered from constant vomiting when any food was taken, the stomach being able only to retain temporarily a very small quantity of fluid. Manual examination suggested an old-standing growth of the stomach, apparently about its centre, and involving a considerable area of the organ. A vertical incision was made, and the stomach exposed. An extensive growth occupied in an annular fashion the middle third of the viscus. As far as could be made out, no gas could be driven from the small portion of the remainder of the cardiac end, which was free into the portion of the stomach beyond the growth. Indeed, the patient had been kept alive with nutrient enemata for a considerable time. The upper part of the jejunum was divided and the distal section connected with the cardiac portion of the stomach. The proximal part of the jejunum was then put into the distal portion of the same gut at a convenient distance from its communication with the stomach. Considerable difficulty was experienced in effecting the connection with the stomach because of the smallness of the area of the cardiac end unaffected by growth, and because of its fixation. Mr. Lane pointed out that the period in the course of the disease in which the operation was performed rendered any attempt at partial or complete excision of the stomach impossible, as the growth was so extensive, and besides there was much glandular infiltration; still the procedure adopted, he thought, would render the remainder of the patient's life less miserable than it had been previous to operation. Mr. Lane considered that this method was certainly accompanied by much less risk and discomfort to the patient than the older manner of operating, while at the same time it was performed with great ease. By means of this operation, he said, any regurgitation of food from the small intestine into the stomach is avoided, and the risk of kinking is *nil*. He also preferred to establish the junctions without any mechanical aid whatever.

**OPERATION FOR THE EFFECTS OF CHRONIC CONSTIPATION.**—The same surgeon operated on a woman, æt. 35, whose recent life had been a burden to her from the pain and discomfort she experienced in consequence of chronic constipation. Besides the appearance of premature senility, which, Mr. Lane pointed out, was always a consequence of the auto-intoxication present in these cases, she had the usual local pain below the last rib on the right side, the tenderness and fulness in the right iliac fossa, frequently accompanied by a fulness in the pelvic region, with pain and discomfort in the vicinity of the sacrum, and in addition all the other symptoms found in this

condition. An opening was made in the left groin through which the transverse colon immediately prolapsed. Mr. Lane drew attention to the fact that in these cases the transverse colon forms a U with its convexity downwards, frequently reaching into the pelvis. The whole of the true pelvis was occupied by the distended cæcum, the end of the ileum entering it to the left of the rectum; the sigmoid flexure was so shortened up and bound down by the adhesions which had formed about it that it would have been unwise, Mr. Lane said, to attempt to utilise it; fortunately, as is usually the case, the rectum was much dilated and elongated, and its walls were considerably hypertrophied. The ileum was cut through about six inches from its termination, between a couple of encircling ligatures; the ligatured stumps of bowel were then inverted by purse-string sutures, which passed through the peritoneum and muscle at a suitable distance from the ligature; the proximal end of the ileum was then connected laterally with the rectum, an aperture of communication of considerable size being effected. Mr. Lane said that the risks of the operation are much reduced by prepurgation and previous frequent irrigation of the colon by some suitable antiseptic lotion. Mr. Lane remarked that the results of these operations for the condition consequent on a habitual overloading of the cesspool have proved at least as satisfactory as he had anticipated. The risk associated with the operation he considered to be very small, whilst the benefit the patients derived both in comfort and in the condition of their nutrition is remarkable. The subsequent progress of the case was most satisfactory.

**OPERATION FOR BADLY UNITED FRACTURE.**—The same surgeon operated on a man, æt. 40, for complete physical disability which was consequent upon a spiral fracture of the right tibia and fibula, the disability being caused by a considerable overlapping of the bones, which were connected together by a quantity of callus, which occupied the interval between them. Owing to the alteration in the axes of the fragments to one another, the patient was unable to walk securely. An incision was made over the tibial junction, and the seat of the fracture freely exposed. The axes of the fragments were accurately defined, and sections were made through each at an angle of 45° in such a manner that the tibial surfaces could be brought accurately together after the bone intervening between the two sections had been removed. The surfaces were brought into accurate apposition, and were retained immovably by a couple of stout silver wires, which passed through the extremities of both fragments. By means of this operation, Mr. Lane said, the axes of the fragments were rendered identical.

### St. Vincent's Hospital, Dublin.

We have been asked to state that the Inaugural Address which was announced to be delivered at the opening of the winter session of the above hospital, on Tuesday, October 4th, has been unavoidably postponed until Tuesday, October 11th.

### Apothecaries' Hall of Ireland.

THE quarterly examinations will take place on the following dates in October:—The first professional will commence on Monday, October 17th, 1904. The second professional, on Thursday, October 20th; the third professional, on Monday, October 24th. All entries must be lodged at least fourteen days previously with the Registrar, 40 Mary Street.

REGISTERED FOR TRANSMISSION ABROAD.

**The Medical Press and Circular.**

Published every Wednesday morning, Price 5d. Post free, 5½d.

**ADVERTISEMENTS.**

Own Insertion:—Whole Page, 25 0s. 0d.; Half Page, 12 10s. 0d.; Quarter Page, 6 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &amp;c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

**SUBSCRIPTIONS.**

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 22s. 6d. credit rate.

**The Medical Press and Circular.**

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 28, 1904.

**ORAL INFECTION.**

ONE of the recent developments of Listerian principles is to be found in the increased attention paid not only by dentists but also by general surgeons to infective conditions of the mouth. It is, of course, obvious that the mouth can never be made, even if it were desirable to make it, absolutely aseptic. The buccal cavity is possessed of its normal flora just as the skin and intestines are; no amount of care and no expenditure of antiseptics can ever render any of them sterile. In the case of the mouth several pathogenic organisms are so commonly present that in judging their significance one has to reckon rather with their numbers and virulence than with their actual presence. It is precisely on account of these bacteria finding a normal *habitat* in the mouth that minor conditions of disease and injury of the buccal tissues constitute a menace disproportionate to their actual extent. The interest that is now being taken in the subject is evidenced by the fact that oral infection formed a subject of debate this summer at both the British Medical Association meeting and at the annual session of the American Medical Association, and that large numbers of surgeons put in an appearance in the respective dental sections of those meetings to take part in the discussions. Diseases of the teeth and contiguous structures are apt to be regarded by medical men as belonging too exclusively to the province of the dentist, but it should not be overlooked that although much of the treatment may have to be carried out by the latter, the responsibility of making the primary diagnosis usually falls on the general practitioner. For he it is whom the patient first consults, and his will be the delicate task of deciding whether the condition of the mouth is secondary to some disease of the whole system, or whether the buccal affection is the

primary cause of the constitutional symptoms. The blood supply of the gums and dental pulp is a terminal one, situated at some distance from the centre of the circulation, so that it is not surprising that in states of impaired or perverted nutrition these structures are some of the first to suffer. With their resistance thus lowered, the teeth and gums become a ready prey to the pyogenic organisms of the mouth, and the interesting condition now known as pyorrhœa alveolaris is a not infrequent sequela. The differentiation of this affection from an ordinary alveolar abscess is most important, as not merely is the dental procedure required for its cure totally different, but the general ill-health at the root of the trouble calls for special treatment according to its nature. Moreover, if the practitioner is on his guard he will perhaps be able to avert the onset of pyorrhœa alveolaris if he includes in his directions to the patient instructions as to the proper cleansing and rubbing of the teeth. When pyorrhœa alveolaris has already set in, the sufferer should be placed as soon as possible in the hands of a scientific dentist so that all tartar and concretions about the teeth may be removed, and the whole visible surface polished and thoroughly cleansed. By this means, combined with continued local lavage and general constitutional treatment, the patient will be placed in the best circumstances for bringing about a cure of this troublesome disease. Although it is pyorrhœa alveolaris following some general affection that comes most frequently to medical notice, there are still other general affections which result from pyorrhœa alveolaris of purely local origin. These affections generally assume the form that it is fashionable at the present day to call auto-intoxication, and pyorrhœa alveolaris set up by neglect of the teeth or by accidental circumstances may gravely undermine the vitality of the whole system by continually pouring into the mouth morbid discharges of a purulent character. The persistent absorption of the bacterial toxins contained in such discharges cannot but be baneful, and it is more than probable that local derangements of the throat and stomach are also caused by this action. Dr. Rhein, whose paper introduced the discussion in the Section of Stomatology at the Session of the American Medical Association this year, made a very suggestive point in connection with the evil of oral infection. He animadverted on the strange anomaly that the strictest asepticism is secured in all surgical appliances during an operation, and that every part of the patient in the neighbourhood of the wound is rigorously treated with disinfectants, whilst the mouth is entirely overlooked as a possible source of infection. Not only ought it to be impossible for secretions of the surgeon's and his assistants' mouths to contaminate the wound—an event guarded against in some hospitals by the wearing of respirators—but in operations on the alimentary tract the patient's own mouth ought to be considered as a potential source of danger, and brought into a condition of the greatest possible cleanliness. Almost precisely similar remarks

were made by Mr. Godlee at the British Medical Association meeting, whilst he further pointed out the improvements in the results of operations on the mouth due to the greater care expended on securing oral cleanliness. The dangers of infection from unhealthy conditions of the mouth cannot be too seriously pondered over, and watched for, by medical men.

#### THE SEIZURE OF TUBERCULOUS MEAT.

THE development of a systematic study of the comparative pathology of tuberculosis shows that we have still much to learn regarding the nature of that disease. It is also becoming clear that the dogmatic assertions of many alarmists are not in accordance with scientific fact or homely common sense. We are glad, therefore, to receive rational direction even from such a conservative body as the Local Government Board. The Board has considered the Report of the Select Committee of the House of Commons on the Tuberculosis (Animals) Compensation Bill of this year, wherein reference is made to the variety of practice existing with regard to the amount of tuberculous deposit in a carcase held to justify its total condemnation. They have also considered the complaints made by butchers as to the injury caused by their prosecution in open court for having tuberculous meat upon their premises. An official circular has now been sent out to the Councils of Metropolitan and other Boroughs and of Urban and Rural districts. Speaking generally, it is most desirable that there should be as far as possible uniformity in the practice of meat inspection. The principles laid down by the Royal Commission on Tuberculosis in 1898 furnish rational and trustworthy directions. The entire carcase and all the organs might be seized when there is miliary tuberculosis of both lungs, when tuberculous lesions are present in the pleura and peritoneum, when tuberculous lesions are present in the muscular system, or in the lymphatic glands, embedded in or between the muscles, and when tuberculous lesions exist in any part of an emaciated carcase. If otherwise healthy the carcase shall not be condemned, but every part of it containing tuberculous lesions shall be seized when the lesions are confined to the lungs and the thoracic lymphatic glands, when the lesions are confined to the liver or pharyngeal lymphatic glands or any combination of the foregoing, but are collectively small in extent. We are pleased to find that the Board are of opinion that at the present time there is no need for any further increase in stringency, but they very rightly insist on the importance of action in strict accordance with the principles which have been laid down. It is also a judicious instruction that if a butcher who is in possession of tuberculous meat has notified the fact to the proper authority as soon as he could be reasonably expected to be aware of it, the case should not be taken into court. We are certainly not a logical people, and as a nation our scientific instincts are not notable, but in dealing with morbid conditions generally, Englishmen may

usually be counted on as willing to adopt and comply with any reasonable directions based upon established scientific facts. We may congratulate ourselves that the "medical advisers" to the Local Government Board are at least free from the all too prevalent phobia regarding the dangers of tuberculosis.

#### INFANTILE DIARRHŒA.

THE important subject of the relation of infantile diarrhœa to public health has received concise and practical treatment at the hands of Sir Charles Cameron, the Medical Officer of Health of Dublin, in a recent report to his Public Health Committee. The disease is one which is increasing year by year in our large cities, and under modern conditions is likely to go on increasing, unless strong measures are taken to prevent its spread. In America it has proved during the last half decade such a veritable scourge that its prophylaxis and treatment are regarded as one of the most serious problems that confront the sanitarian. In these countries, partly owing to difference of climate, and partly to different customs of nursing, it has not yet become so widespread, and consequently has not received the attention it deserves. The rates of mortality quoted by Sir Charles Cameron, however, show that it can no longer be neglected, and that it is tending to become the cause of a large proportion of deaths occurring in young children. In Dublin the death-rate from this cause is comparatively low, in no week rising above 5.5 per 1,000 living, though when we remember that infantile diarrhœa is a preventable disease, this still represents an appalling waste of life. In other cities—Liverpool, York, Hull, Salford, Walsall—it is much higher, reaching the highest point of 16 per 1,000 in East Ham. Without going into the question of the bacterial causes at work, a subject which is being thoroughly investigated in the States, there is no doubt that practically speaking, unsuitable food is responsible for infantile diarrhœa. Among the cases whose history Sir Charles Cameron was able to investigate, out of seventy-four infants under one year old who died from this cause, only eleven were at the breast. Of twenty-five children over one year old, nineteen took ill after the nursing by their mothers had ceased. As nursing at the breast is the rule in Dublin, and feeding by the bottle the exception, it will be seen that the incidence of diarrhœa on those who are bottle-fed is enormously greater than on breast-fed children. The higher rates we have mentioned as occurring in some of the larger English cities are probably due to the greater frequency of bottle-feeding in them than in Dublin. The bottles are rarely kept clean, and when rubber tubes are attached, they are usually simply culture-fields of bacteria. When not in use, the bottle is commonly laid on the window-sill and exposed to street-dust, but not infrequently its resting-place is the even more insanitary coal-hole, dirty cupboard, or hob. In many cases the milk with which infants have been fed has been kept from the previous day,

and of course in impure surroundings. In addition to milk it is extraordinary what things mothers give their young children as food. Sir Charles Cameron's list for infants under a year old includes cabbage, potatoes, fruit, meat, fish, bread, rusks, and various artificial foods, while he notes the not uncommon habit of administering porter as a sedative. It is to be remembered that this system of dirty and bad feeding is in nearly every case the result of sheer ignorance, and but rarely due to a criminal carelessness. The mother does not intend to injure the child—she merely feeds it, as perhaps she herself was fed, and as her neighbours feed theirs. She, indeed, finds it hard to believe that the child's illness is due to any preventable cause, and she is astonished and insulted at the suggestion that the food is bad or the bottle dirty. It is here that much good can be done by education. Instruction in elementary hygiene should be given in the primary schools, for the Board-school pupil of to-day is the parent of a few years hence. And indeed, instruction has very often a wonderful way of filtering through the children to the elders at home. The employment of intelligent female visitors to the houses of the poor can also do much good, but they must have tact, or their advice will be worse than futile. Perhaps one of the most pregnant suggestions ever made with regard to the etiology of summer diarrhoea was that of Dr. F. J. Waldo in his Milroy Lecture some years ago. He surmised that the peculiar incidence of the malady in towns might be explained by food contamination by dust charged with the bowel organisms of lower animals, especially the horse. There is, perhaps, no disease whose prevention is more completely in our hands than infantile diarrhoea, and the responsibility is with our sanitary authorities to make it, as a cause of death, a vanishing quantity.

### Notes on Current Topics.

#### The Weekly National Bill of Health.

THE weekly returns of births and deaths in London and seventy-five other great towns of England and Wales are fountains of perennial interest. The total deaths registered for the week ending September 17th corresponded to an annual rate of 17.0 per 1,000 of their aggregate population. A rate of 17.0 represents a good average, although far above the standard ideal aimed at by zealous sanitarians. In the preceding three weeks the rates had been 20.5, 18.2, and 17.5. The highest annual death-rate per 1,000 living, as measured by last week's mortality, were from all causes, 25.1 in Hull, 25.5 in Sunderland, 26.1 in Hanley, 27.8 in Salford, and 31.6 in Wigan. The fallacy of taking a single week, however, is shown by taking a town like Liverpool, where the mortality for the four last weeks has been 29.4, 27.2, 24.7, 22.3; and in Bootle, with 30.4, 28.7, 23.6, 17.7. Sunderland, on the other hand, has been 19.3, 19.7, 18.3, 25.5. Hull has been fairly consistent with 26.5, 26.3,

21.2, and 25.1; Wigan, 31.6, 25.7, 29.9, and 31.6; while Salford has returned 33.5, 26.6, 23.7, 27.8. Preston, which formerly had a bad record, showed 19.5, 22.2, 21.3, and 19.0. One death was reported from small-pox in the provinces and one in Glasgow. A large number of deaths were due to diarrhoea. In London the mean average of patients in the infectious hospitals during the past thirteen weeks was: small-pox, 38; scarlet fever, 1,753; diphtheria, 771; and enteric fever, 93.

#### Pharmacy Law in the Transvaal.

THE Transvaal Pharmacy Ordinance, which last month became law, by the assent of Lord Milner, contains several points which are distinctly in advance of the position of pharmacy law in these countries. In reference to the much-vexed question of company proprietorship of druggists' shops it is provided that the managing director of the company shall be in all cases himself a registered "chemist and druggist," and that the name of the assistant managing the shop or branch shall be posted in a prominent place in the shop. Even more stringent is the regulation that for an offence committed by a company every director shall be responsible, just as if the offence were committed by him as an individual. This, we understand, is a reform for which the Pharmaceutical Society at home is striving. As regards the sale of poisons strict rules are to be enforced. A penalty of a fine up to seventy-five pounds, or six months' imprisonment, is named for the offence of keeping or selling poisons without labelling them "poison," while lesser fines or terms of imprisonment are named for other offences. We think the power to send to prison in these cases is a very useful one, and we should be glad to see clauses embodying it added, not merely to our own pharmacy laws, but to the licensing laws in general.

#### Lesions in Movable Kidneys.

ABNORMAL mobility of any organ of the body does not in itself constitute a disease, though it is quite common to find that such increased freedom of movement or, it may be, actual displacement induces reflexly a train of symptoms which may be productive of life-long suffering. In the case of the pelvic viscera this is especially noticeable. The liability of an unduly mobile or misplaced organ to disease has many times been discussed, but clinical evidence would seem to prove that it is not more likely to undergo structural change than one which is normally in position, unless adhesions are contracted between itself and the neighbouring tissues. With regard to the kidneys, it is frequently observed that alterations in their position are found in neurotic subjects, though the reason for this is not quite obvious. The association of a movable or floating kidney with gall-stones is well known, and displacement or ptosis of other organs may be present at the same time. Kinking of the ureter occurs sometimes, but with less frequency than might be supposed. Intermittent hydronephrosis should, therefore, be a common

occurrence in cases of considerable mobility, and this would eventually lead to degenerative changes in the kidney itself. In a series of cases in which the operation of nephropexy was performed at the Chelsea Hospital for Women, Mr. Frank E. Taylor (a) has found that unsuspected lesions were discovered in no less than 10 per cent. Three cases are reported, in two of which the misplaced organ contained a calculus, while the third proved to be one of renal tuberculosis. Two other cases are also described in which the organ was hydro-nephrotic as well as movable. The inference to be drawn from these observations is that the kidney should be carefully examined at the time of operation, special attention being paid to any doubtful-looking spots.

#### A Medical Journalist.

THE brilliant journalistic feat of Dr. G. E. Morrison in securing for the *Times* the full text of the new treaty with Tibet, about which so much mystery hung, brings into prominence again the name of one of the members of the medical profession who have found fame in other fields than that for which they were designed. Born under the prosaic roof of Geelong College near Melbourne, the spirit of adventure early seized Morrison, and he first distinguished himself by voyaging in a canoe the whole length of the River Murray, which is to Australia what the Mississippi is to America. Not content with this, he next walked across the Australian continent from north to south, writing an account of his wanderings for the *Melbourne Age*. The same paper sent him on a voyage in a trading schooner among the Pacific Islands, and subsequently to New Guinea as leader of an exploring expedition. There his career nearly came to an end for he was badly wounded by a native spear; in fact, part of the weapon remained in his body for many months and was only finally extracted at Edinburgh, whither he had gone to study medicine. After graduation, Dr. Morrison started off on his travels, once more finding his way to the Rio Tinto mines in Spain, where he officiated as medical officer, and to Ballarat, where he was appointed the superintendent of the district hospital. It was, however, at Pekin as Special Correspondent to the *Times* that he found his *metier*, and few will forget his well-informed and prescient telegrams on the events preceding the Boxer rising. Lord Curzon, then Under-Secretary for Foreign Affairs, had finally to confess that the *Times* was better informed than the Government. Medicine seldom leads its followers to fame as journalists, but so long as it possesses in its ranks men of the type of Dr. Morrison, it will have no cause to be ashamed of its performances in this respect.

#### Moral Imbecility.

THE condition to which the term moral imbecility has been applied should be understood and recognised by all teachers and trainers of the young, for thus only can its unfortunate subjects be pre-

vented from disgracing themselves and doing injury to others. Medical treatment is not likely to be of any use, but an early diagnosis may be the means of enabling the guardians of a child to deal firmly and wisely with him. A shocking case of a moral imbecile occurred recently in America. The subject was a sick nurse, aged forty-five, and when she was finally brought to book it was found that she had fatally poisoned some twenty people, besides having attempted arson on several occasions. Her favourite plan was to administer the lethal drug in Hunyadi János water, but sometimes she did so by enema—always, however, so combining the poison with other drugs that its characteristic effects were masked. She was not the subject of any delusions or fancied injury, but appeared to be actuated by a sheer reckless love of destruction. It came out that her father had been eccentric in his habits, whilst one of her sisters was a chronic dement and another a prostitute. She herself had been a troublesome child, given to lying and deceit, and though entered at two-training schools as a nurse she had been dismissed from both. Her lying propensities had been recognised at these institutions, and she was regarded as untrustworthy in character and peculiar in manner. Under the circumstances it is little less than astonishing that she should have found employment as a private nurse, but such was the case, and the disastrous result already mentioned followed. At her trial a commission of three medical men was appointed to inquire into the state of her mind, and they had no difficulty in finding that she was not responsible for her actions. She was removed to a State hospital for care and restraint, and within a year developed delusions of poisoning and hallucinations of hearing, accompanied by marked impairment of initiative. That a woman of this kind should have been allowed to continue for years in the enjoyment of public confidence in a civilised country is barely credible, and we think her career forms an argument for the State regulation of nurses, both in this country and America, although under any system the difficulty of detecting the early stages of mental disease and irresponsibility would obviously remain.

#### Bechterew's Reflex.

A NEW reflex promising some aid in the diagnosis of lesions of the spinal cord is described by Bechterew, (a) and its presence and significance are corroborated by the fact that they have been independently discovered and described by another physician, Mendel. This reflex is somewhat analogous to Babinski's, and can sometimes be obtained when the latter is uncertain or altogether absent. Bechterew's sign is elicited by striking lightly over the dorsum of the foot at the base of the toes, when immediate flexion of the digits follows in certain pathological conditions. If the sign is well marked, there may be also abduction of the toes, but the essential feature is the flexion. It does not occur in perfectly healthy persons, but only when an organic lesion of the pyramidal tracts of

(a) *Annals of Surgery*, August, 1904.

(a) *Obozrenie Psichiatii*, June 1904.

the cord is present, so that its significance is much the same as that of Babinski's sign. In some cases a similar reflex can be elicited, according to Bechterew, in the hand, percussion over the carpo-metacarpal joints producing flexion of the fingers. While the difficulty of diagnosing organic from functional diseases of the nervous system continues to be so great, one is thankful for every little aid in clinical work, and if the new reflex is as trustworthy and helpful as that of Babinski has proved itself, it may be cordially invited to take its place in the category of physical signs.

#### Antiseptic Value of Iodoform.

THERE are few things so touching in recent practice as the love of the surgeon for iodoform. Far from being repelled by its odour he seems to positively revel in it, and as to reports from bacteriologists saying that it is neither aseptic in itself nor antiseptic when applied to wounds, he continues to regard such assertions as calumnies upon an old and valued friend. Enterprising firms bring out all sorts of elegant substitutes, but the surgeon passes them by unheedingly, and even occasional cases of iodoform poisoning do not deter him from scattering it freely on the next wound he encounters. After all, it seems, he is right. A reassuring paper on the subject has been published by Heile (*a*) as the result of some careful work he has done in the University Laboratory at Breslau. He found that iodoform under favourable conditions is broken up in the tissues, and that a body called di-iodoacetyliden—a powerful antiseptic—is given off. But for this action to be brought about the tissues must be allowed to act on the iodoform in the absence of air, when if the medium be alkaline the formation of di-iodoacetyliden goes on for a long time. Under such conditions an antiseptic value far higher than that of corrosive sublimate is attained by this new body, and thus it would seem that for once, at any rate, the clinical instinct of the surgeon has triumphed over the theories of bacteriologists. But it is important to notice that the formation of di-iodoacetyliden takes place only anaerobically, and therefore the sprinkling of open wounds with iodoform would not seem to be of much service. On the other hand Heile's researches, which we hope may be extended, supply a rational basis for the use of the iodoform gauze plug and drain to deep wounds, and it is satisfactory to know that this practice of the many eminent men who prefer iodoform gauze to any new product of the laboratory is apparently well founded.

#### The Cell and Immunity.

EVER since the disappearance of the old "exhaustion theory" of immunity, due in the first instance to Pasteur, two rival theories have contested the field, and it is only in these days that a final agreement between them seems possible. On the one hand there were those who held with Metchnikoff that the important factor in immunity

was the leucocyte, and that its so-called phagocytic function explained the facts sufficiently. On the other hand, Buchner and, in general, the German school held to a "humoral theory," believing that the protective bodies existed, not in the cells, but in the fluids of the body. Opposite and apparently irreconcilable as these two views were, Buchner made the first step towards uniting them by his expression of opinion in 1894, that the protective bodies—or alexins, as he termed them—although found in the fluids, were a secretion of the leucocytes. He regarded phagocytosis as of secondary importance. It, however, has been stoutly and consistently defended by Metchnikoff, and although at one time most inquirers other than those immediately influenced by him had ceased to attach much importance to it, it seems by the latest observations to have undergone a certain reinstatement. This has taken place as a result of the discovery by Wright and others of bodies called "opsonines," whose presence in the serum is necessary to enable leucocytes to exercise phagocytic powers. It is only, then, by a constant interaction of serum and cell that immunity is possible. On the one hand, the antitoxic and antibacterial bodies are in all probability secreted by the leucocytes and certain of the body-cells, while on the other, the phagocytic activity of the cell is only exercised in the presence of certain bodies supplied by the serum.

#### Private Hospitals.

ONE of the most noticeable changes in medical practice in our generation is the sudden and great growth of private hospitals. There is no doubt that in many forms of disease more suitable treatment and greater care can be given to a patient in a private hospital than is possible in his own home. In surgical cases, for instance, where operations are to be performed, they can be done with greater safety to the patient and much greater convenience to the surgeon in a room specially designed and kept for the purpose than in a hastily fitted bedroom in a private house. On the point of economy, too, the private hospital presents obvious advantages over the home. Instead of a patient requiring, as at home, the entire services of one or two nurses, a number of patients can be efficiently attended by one nurse. The cooking of food, too, and the preparation of invalid necessaries of every sort, is done as a matter of routine by those who are accustomed to it, while in a private house a sick person can often only receive due attention at the expense of the comfort of the entire household. Considering the many advantages on the side of the private hospital system we cannot wonder at its general adoption, and we may expect a still further extension in the future. With this increase, however, there will be considerable need of caution as to the management of many of the nursing homes which are likely to spring up. The custom which obtains in some homes at present of providing untrained women as nurses is strongly to be deprecated.

(a) *Archiv f. Klinische Chirurgie*, Vol. lxxi., p. 787.

There can be no objection to employing for some period of their probation pupils of a recognised training school in order to habituate them to the nature of private practice, but there is every objection to the permanent employment in these homes of women who have not gone through a regular course of training. Medical men should be very careful as to the qualifications of the nurses employed in the private hospitals they patronise.

#### Soap Tincture for the Hands.

It is probably true that success in sterilising the hands depends rather on the care shown by the individual surgeon than on the method employed. Nevertheless, as every surgeon wishes to make use of the method which is at once most efficacious and least troublesome, it is worth while drawing attention to the *rationale* of the action of alcoholic soap, which has been found successful by many. With the object of discovering the most serviceable antiseptic, Iverck has performed a series of experiments on moulds, and he believes that the best effects can be gained by a combination of watery and alcoholic germicidal solutions. He finds that spores, and probably bacteria, may be divided into two classes. The one kind is coated with a film of air, and is thereby protected against any watery poison, while the other, being coated with a mucous or gelatin capsule, is impervious to alcohol, but easily reached by water. The first part of the process of cleansing should, then, consist in the application of an alcoholic solution of soap, which effectively removes the air and emulsifies the fats of the skin, leaving the germs exposed. Rinsing in watery solution will then wash away or destroy the germs which have escaped.

#### The Artificial Production of Leukæmia.

AN important investigation bearing on the etiology of leukæmia was brought before the recent meeting of the British Medical Association by Dr. Moorhead, of Dublin. His report was only a preliminary one, and, consequently, tentative conclusions are alone permissible, but it is not too much to say that he has succeeded in producing in rabbits a condition bearing many resemblances to leukæmia. Having obtained a supply of lymph glands fresh from a fatal case of lymphatic leukæmia, several extracts, alcoholic, glycerine, and saline, were made. Of these one only, the saline extract, had any power. On infection into rabbits a marked fall of blood pressure took place, while continuous injection produced distinct changes in the blood-forming tissues. Controls with extracts of normal lymph-glands, and of thymus glands, were constantly negative. The principal changes produced by the leukæmia extract, which were remarkably similar in the three animals treated, were hyperplasia of the lymph-glands and spleen, leucocytosis, and softening and other changes in the bone marrow. The probability is that Dr. Moorhead has succeeded in obtaining a soluble toxin of leukæmia, and it is to be hoped that

further experiment on the same lines may succeed in elucidating the causation of one of the least understood of our common diseases.

#### The Management of Diphtheria Suspects.

IN spite of the great strides which sanitary science has made during the last couple of decades, the acute exanthemata do not seem much nearer extermination than formerly. Their virulence certainly seems to have undergone some modification, and that is the only noteworthy change in their life-history. It is a matter for congratulation that the medical profession are at last awakening to the futility of many of the methods which have received the sanction of authority and tradition for dealing with the acute specific fevers. The valuable papers by Drs. Biss, Millard, and others recently published in our columns have aroused an interest in the question which is the inevitable precursor of a thorough and systematic inquiry. There is one disease — diphtheria — so insidious in its onset that its presence may be wholly unsuspected. When this affection is epidemic there is always a considerable difficulty in determining the true clinical diagnosis in doubtful cases, and, in fact, the universal practice is to let the bacteriologist decide the question. Even when the report is in the negative, cases frequently occur in which the after-progress shows that the disease must have been one of true diphtheria. According to the annual report of the medical officer of health for Bristol, 1,134 cases were notified as diphtheria (including membranous croup) during 1903. Dr. D. S. Davies pointed out the great significance of the presence of the Hoffman bacillus in the nose and mouth of children who have been in direct association with cases of clinical diphtheria, and he considers that such scholars act as "carrier" cases. For such "suspects" the plan of opening an out-patient hospital, where the necessary local treatment has been applied by skilled nurses under medical supervision, has been found to work well. In this manner we learn that a more serious local outbreak was happily prevented.

#### "Breathing out Slaughter."

IF it be true that "many a true word is uttered in jest," it is equally certain that many of the quaintly-turned phrases and poetical ideas of the ancients contained such germs of truth as to place them on the level of prophecies. The expression, "breathing out slaughter," stripped of its poetic imagery and read in the light of modern bacteriology, becomes transformed into a bald statement of scientific fact. In other words, we are beginning to learn that the act of respiration is not quite so innocent as was formerly supposed, and that the air around us may be contaminated to a considerable degree by the organisms exhaled in the breath of every individual. Many of these bacteria are normal inhabitants of the mouth, and are non-pathogenic, but others may be the germs of specific

disease. With regard to the tubercle bacillus, the latest researches appear to show that the number of bacilli ejected in this manner in ordinary quiet respiration is so small that it may be disregarded, whereas the act of coughing is accompanied with danger to all around. The report recently issued by the Local Government Board devotes considerable space to the investigations undertaken by Dr. Mervyn Gordon into the contamination of air by various respiratory acts, such as coughing, singing and speaking. It has thus been ascertained that bacilli and streptococci are capable of being wafted to as great a distance as forty feet in front of a speaker, and the experiments of Nenninger are quoted to the effect that the *B. prodigiosus* may penetrate as far as the smaller bronchi of animals made to inhale the spray of an emulsion of this organism. This new phase of air-borne infection is worthy of consideration by those who have the interest of preventive medicine at heart.

#### The Incorporated Medical Practitioners' Association and the Midwives Act.

THE Council of the above body has at a recent meeting passed the following resolution regarding the action of the Central Midwives' Board in deciding to appoint unqualified women as examiners for the certificate of the Board:—"That we, the Council of the Incorporated Medical Practitioners' Association, at this our first meeting since the vacation, desire to place on record our protest against the action of the Central Midwives' Board in deciding to appoint as examiners for the certificate of the Board non-medical women, thereby raising to the level of the duly registered medical practitioner, who has undergone an expensive course of study and a searching examination, women who are not required to show proof that they possess any knowledge of the different subjects which a medical practitioner has to study in order to obtain a diploma." We thoroughly sympathise with this resolution and trust that other medical bodies in England and Wales will come forward and make a similar protest. The actions of the Central Midwives' Board since it commenced its existence have been in many instances apparently dictated by a spirit of opposition to the medical profession, and we regret to say that certain of the medical members of the Board have not made the firm stand against such actions that might have been reasonably expected.

THE forthcoming visit of French physicians and surgeons to London will take place from October 10th to 12th. It expresses in a particular form the general spirit of the *entente cordiale* between British and French citizens, and is therefore deserving of every encouragement at the hands of so loyal a body of citizens as the members of the medical profession. It is announced that the chairman of the Paris committee has written, stating that his party would probably include about fifteen professors of the Faculté de Paris, thirty physicians and surgeons of Paris hospitals,

seven teachers of provincial medical schools (lists on the table), fifty M.D.'s from various parts of France, and probably about thirty or forty internes, also that the party will be accompanied by twelve ladies. A number of hospitals and laboratories will be visited, as well as various workhouse infirmaries and Metropolitan Asylums Board hospitals. The entertainments include a luncheon provided by the *Lancet*, and a dinner held on October 12 at the Hotel Cecil.

#### PERSONAL.

INSPECTOR-GENERAL DUNCAN HILSTON, M.D., C.B. has been appointed Honorary Physician to the King in place of Inspector-General D. McEwan, deceased. Dr. Hilston, who joined the service in May, 1860, and retired in 1897, has seen active service in New Zealand when he was mentioned in despatches.

THE address at the opening of the Medical Faculty of the University of Birmingham will be delivered by Dr. P. H. Pye-Smith on October 3rd.

DR. J. N. McDOUGALL, of Coldingham, Berwickshire, was recently presented with a brougham by friends and patients.

THE opening address of the West London Post-Graduate College will be delivered on Thursday, October 13th, by the Bishop of Oxford.

MR. C. M. TUKE is the President for 1904-05 of the West London Medico-Chirurgical Society.

DR. GRAHAM BLICK has been appointed acting Resident Magistrate in charge of the Broome District, West Australia, and Chairman of the Broome Quarter Sessions.

ANY medical man resident in London who wishes to attend the dinner at the Hotel Cecil, to be given to the French physicians and surgeons on October 12th, should communicate with one of the Honorary Secretaries, Dr. Dawson Williams or Dr. W. Jobson Horne.

DR. LEITH NAPIER, of Adelaide, formerly one of the staff of the Chelsea Hospital for Women, has brought an action against the Government to recover £6,500 damages for fracture of the base of the skull sustained from a fall from a horse whilst serving on a contingent about to be dispatched to South Africa.

ON the occasion of their golden wedding, Dr. and Mrs. Latimer Parke, of Tideswell, Derbyshire, were last week presented with a handsome testimonial by residents of the Peak district, where Dr. Parke has been in practice for fifty-four years.

THE exhibition of the Institution of Hygiene in London will be opened by Sir Joseph Fayrer, K.C.S.I., on Friday next.

H. M. THE KING has been graciously pleased to confer the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force, who have been duly recommended for the same under the terms of the Royal Warrant, dated July 28th, 1892:— Surgeon-Major A. Lugard, 3rd Middlesex R.G.A.; Brigade-Surgeon Lieut.-Colonel W. D. Waterhouse, 4th V.B. Royal Fusiliers; Surgeon-Major E. Haydon, M.D., Hay Tor V.B. Devonshire Regiment; Surgeon-Lieut.-Colonel F. K. Pigott, 1st V.B. the King's Shropshire Light Infantry; Surgeon-Major J. G. Saville (retired), V.B. Manchester Regiment; Surgeon-Major W. L. Stewart, M.D., 1st Banff R.G.A.; Surgeon-Major R. Kerk, M.D., 8th V.B. Royal Scots; Brigade-Surgeon Lieut.-Colonel F. H. Appleby, 5th Notts V.B. the Sherwood Foresters.

**Special Correspondence.**

[FROM OUR OWN CORRESPONDENTS.]

**SCOTLAND.**

**NEW HOSPITALS IN GLASGOW.**—The hospital equipment of Glasgow has received an important addition by the opening of the new buildings at Hobhill, Duke Street, and Oakbank, which have been in course of erection for nearly four years. The buildings have been constructed by the Parish Council at a cost of nearly half a million, with the object of treating the sick and infirm poor separately from other paupers. The Hobhill Hospital has grounds to the extent of fifty-four acres, and is designed for the accommodation of 1,600 patients—the infirm poor, and children. The blocks containing the fourteen medical and surgical wards are built in two storeys each; the wards accommodate twenty-six patients in the main ward, and have side rooms for one or two beds in addition. There are also four two-storey blocks for the aged and infirm, isolation blocks containing four bed wards, and a children's section consisting of thirteen two-storey blocks, a school, and a building to accommodate 100 children likely to be in residence only a short time. Ample administrative buildings have also been provided. The Eastern District Hospital in Duke Street has accommodation for 200 patients, while provision has also been made for the treatment of about fifty mental cases. There are besides wards for medical, surgical, skin, and obstetric cases, isolation and observation wards, an operating theatre, mortuary, post-mortem room, and pathological laboratory. One special feature has been introduced—the radiation of wards from a common centre with the object, rendered necessary by the restricted space at the architect's disposal, of economising the ground occupied by corridors and staircases. The Western District Hospital comprises eight blocks, affording accommodation for 200 patients, and including administrative block and surgical, medical, maternity, and skin pavilions. Throughout the buildings there has been no attempt at ornament or decoration and the furnishing is of the plainest and simplest description. The policy of the Council has been, and wisely, to obtain the largest amount of accommodation at the smallest cost, along with all the most modern improvements and appliances for the benefit of the patients. The buildings were formally opened by Mr. George Dolt, chairman of the Council, on September 15th, and after the ceremony the party proceeded to Woodilee Asylum, another of the Council's undertakings, to inaugurate a new nurses' home, which has been necessitated by the increased number of nurses resulting from the introduction of female nursing into the male wards, and the handing over of the complete management of the sanatoria to women nurses.

**BELFAST.**

**SMALL-POX IN ULSTER.**—The outbreak of small-pox seems to be about at an end in Ulster. During the past week no new case has occurred except one in Monaghan, and as that was in a suspected family who had been under observation, and was at once isolated, it is not likely to be followed by others. The local authorities are now engaged in paying the bills incurred during the outbreak, not the least of which are those for vaccination, and from the remarks made at various public boards it is clear that if the payment of vaccination fees was not provided for by Act of Parliament the medical profession would fare badly.

**THE USE OF SALICYLIC ACID.**—An interesting case came before the Recorder of Belfast last week, in which the question at issue was the harmlessness or otherwise of the addition of salicylic acid to ginger wine, to the extent of 7.2 grains per pint. There was a great array of medical evidence, but, unfortunately, it was of that contradictory character which gives some excuse for the layman to scoff. The city analyst said that he believed salicylic acid to be a dangerous drug, which should only be used under medical advice. Dr.

Henry O'Neill said that the ordinary dose was 5 to 20 grains, and above this was dangerous. He gave a vivid picture of the state of collapse that might follow too large a dose. It was specially dangerous to persons suffering from diseases of the heart, liver, or kidneys, and in such its continued use might be followed by death. Dr. S. B. Coates agreed with Dr. O'Neill, and said he would not allow the smallest quantity of the drug to be used as a preservative in food. Dr. Torrens also corroborated this view, but went even further, for he stated that he had once been nearly killed by salicylic acid when he had rheumatic fever, and had never prescribed it since. Sir William Whitla said that though the B. P. dose was 5 to 20 grains, more was often given, frequently even as much as 120 grains a day. This would represent the amount contained in two gallons of the ginger wine, and the sugar in the same quantity, nearly half a stone, would, in his opinion, do more harm than the salicylic acid. The amount contained in the wine he considered absolutely harmless. All the bad effects described by the other witnesses were due to impurities in the drug, which used to be found almost constantly, but were absent now that better methods of preparation were employed. Dr. A. Montgomery was also examined, and expressed his agreement with Sir William Whitla. In summing up the Recorder said that if the drug was not necessary it should not be introduced into the wine, and if it were harmful it should not be introduced. As ginger wine had been used long before salicylic acid had come into use, and there was no evidence that it was better now than then, he was bound to conclude that it was not necessary, and therefore should not be introduced. It appears from this decision that the Recorder avoided giving any opinion on the question of the harmfulness or otherwise of the drug. We are not aware of any medical man who has a special weakness for ginger wine, but if any of us had, we should probably prefer it without the salicylic acid, so see no reason to regret the decision.

**Correspondence.**

[We do not hold ourselves responsible for the opinions of our Correspondents.]

**THE DIMINISHING BIRTH-RATE.***To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Viewing this subject mainly from the same standpoint as Mr. L. W. Hudson, I agree with him that the discussion has been somewhat disappointing. It is especially disappointing to find Dr. Drysdale apparently retiring after contributing a letter full of controversial points and containing at least one dogmatic statement of the most questionable character. Dr. Drysdale has done more than any living Englishman to bring into practice the theoretical views he holds. Since the days of Mr. Bradlaugh and Mrs. Besant, whose colleague he was in the propaganda to which they devoted much of their lives, Dr. Drysdale has, if I mistake not, assumed the position of protagonist in this particular cult. Judging from his utterances he is probably proud to feel that thousands of married couples are acting upon the advice which he has persistently urged upon them. In some cases it is possible parents may be fully justified in limiting the number of their offspring; the danger lies in the creation of an overmastering sentiment of egoism throughout the nation, which may lead to what is practically race-suicide. It is in the influence upon a nation as a whole that I am most interested. Of this influence, when Dr. Drysdale's ideas are carried to their logical conclusion, we have a plain object-lesson in France. In view of this lesson, Dr. Drysdale has the hardihood to express the opinion that "Economically it is out of the question for the people of any European State like ours to think of having large families with impunity." Is he not bound to establish the truth of this statement by an examination of the

economical position of France in relation to the population question? France, with the most fertile soil—a soil capable of supporting many more millions than at present subsist upon it—the most magnificent climate, and the most intelligent populace of Europe, has not enough men for her home requirements. Her numbers are only kept partly up by immigration of Italians, Swiss, and Germans. She cannot spare, and virtually does not send, any emigrants to occupy and develop the vast possessions mis-named colonies—even to beautiful Algeria close to her shores—which she has acquired mostly within late years, so that these form in great part a useless burden, expense, and source of weakness to the State. France is already one-third less in population than Germany, and the disparity is rapidly increasing, so that resumption of her once dominant position in Europe seems for ever hopeless. It is not prudence alone which guides the modern French parent, but rather the narrowest form of anti-social egoism—the egoism which sacrifices everything in pursuit of ease and pleasure, and regards toil and self-abnegation as the sources merely of pain and unhappiness. These ideas are inculcated into the children—who among the well-to-do and wealthy are almost invariably guarded from the stress and fight in life, without which fine character can rarely be evolved. France is a dying nation through shrinkage of population, and she presents besides glaring signs of moral decay. These evils are only to be cured by abandonment of the vices of civilisation and a return to those more primitive, natural, and simpler customs which Dr. Drysdale is doing his best to banish from his own land.

I am, Sir, yours truly,  
A STUDENT OF SOCIOLOGY.

September 22nd, 1904.

#### THE LUNACY QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some years ago I was dining with the late Dr. Forbes Winslow in Manchester Square, when more than forty guests were present, and naturally the subject of insanity was discussed after dinner. The discussion assumed a very amusing character. Three pretty well-known men seemed to have put their heads together in a sportive mood—namely, Dr. Radcliffe, Dr. Clark, of the *Lancet*, and Mr. Ernest Hart. They were sitting nearly opposite to our hospitable host, and they seemed to be intent on provoking him by questions for the entertainment of the table. It ended in their doing this to such an extent as to make Dr. Winslow declare that in his opinion nearly all the world was insane. Of course, if that is really the view of any specialist in insanity, and if it is a correct view, we must find it rather difficult to know when to certify and how to deal with this subject in a moral and legal spirit. Professionally, however, I think we shall agree that when we have to do with a patient whose mind is diseased and who, in our opinion, is not capable of taking care of himself and may be dangerous to others, we ought, morally and professionally, to be careful and in no way be parties to any transactions which will not bear the just and proper criticism of an independent and capable lawyer, or of a jury of good men.

I am, Sir, yours truly,  
ROBERT LEE.

September 22nd, 1904.

#### Literature.

PATENT FOODS AND PATENT MEDICINES. (a)

THIS little book is composed of reprints of two

lectures given by Dr. Hutchison, that on Patent Foods being delivered before the South-West London Medical Society, the second being addressed to the students of the London Hospital. In the discourse on "Patent Foods," the author ingeniously defines a patent food as "a substance which is manufactured by artificial means from natural food products, and which is intended to be used as a substitute for ordinary natural foods, and . . . such foods are usually sold by pharmacists instead of being procurable from the ordinary dealers in common food." Dr. Hutchison then deals with the scientific considerations which might justify the manufacture of patent foods. Briefly, these are: where the patient has no relish for ordinary food, where difficulty in chewing or swallowing is experienced, when there is a necessity for predigested foods, where the physician desires to increase the amount of any particular ingredient in the diet, &c. Almost every artificial food in the market fails to meet the requirement of being reasonable in price, in comparison to the amount of nourishment obtained.

Dr. Hutchison says, "the majority of artificial foods do not correspond to any one of those qualifications I have set out." He goes on to show where they fail, and explains how even those that may be valuable because they contain certain desired constituents are very much more expensive and are no more satisfactory than certain ordinary foods or preparations that are not proprietary. For example, honey is much cheaper than extracts of malt, and contains wholly digested sugar, while that of the latter preparation is only partially digested. He also shows how seldom there is any necessity for predigested foods. Cod-liver oil emulsion, petroleum emulsion and pancreatic emulsion are shown to be practically unnecessary; the place for beef extracts is shown to be in the kitchen, and not in the sick room. Peptone preparations, beef juices, and many other foods are examined, and finally four pages are devoted to showing the composition of infants' foods.

The second lecture, one delivered to the students at the London Hospital, ought to be read extensively both by the medical profession and the general public. Its phraseology is such that the latter class can appreciate it as well as the medical man. Comparatively few people do not have recourse to patent medicines in one form or another, and we are immensely indebted to Dr. Hutchison for calling attention to this important subject. People who have never had occasion to analyse even qualitatively a mixture of three or four drugs (not necessarily official in the British Pharmacopœia) can have no idea of the immense amount of labour which the three pages of analyses of proprietary medicines given on pp. 36-39 must have entailed, and although Dr. Hutchison may have missed one or two unimportant ingredients, the results are ample to show how little justification manufacturers of these "quack" remedies have for their glowing advertisements. Many are palpable frauds, others are mixtures of drugs that are commonly prescribed, and some are ordinary household remedies hidden by colouring matters, &c. With characteristic generosity Dr. Hutchison admits that the makers sometimes recognise that drugs which have fallen into disuse among medical men are still very valuable, but these are the exceptions. Obesity preparations and drink cures are considered, as well as liver pills and cough mixtures, and some very sensible observations are made on the ethics of patent medicines, and finally Dr. Hutchison shows how quackery may be fought. He very justly remarks that the crusade against quackery ought to be undertaken by an official body, and not be left to the initiative of private individuals. We congratulate Dr. Hutchison on the able way in which he has striven to bring home to the medical profession the fact that they can all help in lessening the power of the patent medicine proprietor over the general public, and we hope that these papers will receive the moral and practical support of the profession.

## CLINICAL HANDBOOK OF URINE ANALYSIS. (a)

As the author remarks in his preface, this is an attempt "to place before the clinical student and medical practitioner the essentials of clinical urine analysis in a *brief, simple, and convenient form*."

"The methods described are, as a rule, those which have been most fully studied, and which are at present considered the most suitable for *clinical requirements*."

The opening chapter is entitled "Collection for Analysis," where valuable hints are given as to the best means and conditions of taking samples for the different examinations and the author gives the student the benefit of his experience in the preservation of urine during the time that elapses between micturition and analysis. Then follows a "Scheme of Urine Analysis," and the remainder of the book is divided into two parts: Qualitative Examination and Quantitative Methods. In the chapters on "Physical Examination," the author discusses the causes and significance of variations in quantity, colour, odour, reaction, specific gravity, transparency and the deposit in a most able and satisfactory manner. A consideration of the deposit occupies pp. 24-49, but we should have liked to see the use of such a stain as Jenner's blood stain recommended as being of considerable assistance to the beginner in facilitating the detection of leucocytes, epithelial cells, and other objects likely to be present in the organised deposit. Such a stain is, of course, superfluous after the operator has had much experience in the microscopical examination of the sediment.

Four pages are devoted to the detection of the gonococcus and the bacillus tuberculosis, but it would have been well to add that the gonococcus does not grow readily on gelatine, and for the information of the operator a list of the other organisms found in the urethra and vagina of healthy persons, which resemble the gonococcus, should be given to impress on the student the great care necessary before it is advisable to give an opinion regarding the presence of the gonococcus. Still, the author lays stress on the necessity of using Gram's method of staining, and the presence of the organism *within* the pus cells, and after a little practice it would be impossible for anyone to go wrong if he follows the instructions given. In the figure of gonococci (Fig. 2, Plate III.) the organisms are represented as if they were stained by Gram and the preparation counter-stained with eosin. Probably the figure is taken from a preparation stained with some blood stain, but in order to avoid possible errors due to the seeming contradiction of letterpress and figure, the colouring of this plate should be altered in the next edition. In the footnote on p. 35, the strength of solution of caustic potash used in the preparation of Löffler's alkaline methylene blue is given as 10 per cent. This is obviously a misprint for 0.01 per cent. Both in the case of the gonococcus and the tubercle bacillus, it is always advisable—indeed, most people consider it a necessity—to "fix" the film preparation by passing it three times through the flame. The "Qualitative Chemical Examination" is well written, and we heartily endorse Dr. Bedford's recommendation that in testing for albumin, the heat, nitric acid, and picric acid tests should all be employed. There can be no doubt that traces of albumin are frequently missed because of the slovenly way in which students and others test for it.

Part II deals with quantitative methods, and here the author has to describe volumetric methods in preference to gravimetric, owing to the latter requiring an accurate chemical balance. He, however, makes a very wise choice of the numerous volumetric methods that are in use, but we might point out that in the estimation of glucose by Pavy's method it is advisable to dilute the urine with dilute ammonia, as this greatly lessens the risk of the precipitation of cuprous oxide. Three pages are devoted to calculi, and there is a

chapter on "Cryoscopy" and "Drug Tests of Renal Excretory Power." The book closes with three Appendices and ten plates; the latter are unusually well produced, the exception being that of gonococci in pus cells, mentioned above, and the plate of tubercle bacillus, which would not be of much use to a practitioner who was unacquainted with the organism.

## MILK: ITS PRODUCTIONS AND USES. (a)

DR. WILLOUGHBY is well known in the scientific world and as the contributor of the article on milk for the "Encyclopædia Medica," and his experience is such as to commend the book now under consideration to the notice of all interested in milk. We consider that he is somewhat erring on the side of modesty in considering that his work will chiefly interest medical officers and "gentlemen in the country who engage in dairy work," for it contains matter which, though not strictly analytical, will be of value to analysts, and though not professing to be a farmer's manual, it will appeal to that class owing to the useful information that it contains on the breeds of cows and their relative values from a milk production point of view.

Finally, there is another class of men to whom this book will be exceedingly welcome—namely, sanitary inspectors. These men have not merely to assist in the carrying out of the Foods and Drugs Acts, by taking samples for analysis, but have to assist the medical officers in tracing the cause of outbreaks of disease communicated by milk, and in addition to see to the carrying out of the provisions of the Acts dealing with dairies, cow-sheds and milk-shops.

There has been up to the present no book of convenient size and reasonable price which contains so much information in a concise form. There are analytical treatises which go more fully into the matter of the composition and testing of milk in the laboratory, but these works do not contain the all-round information which is given here.

The book is divided into fifteen sections, beginning with the breeds of cattle, choice of cows, their housing, their food and diseases. After this the legal aspect of disease is dealt with, the Acts dealing with it, the elimination of tuberculosis, and the control of cow-sheds and dairies.

Next the composition of milk and milk products is considered, the relation of milk and disease; after which comes a section on the construction of the dairy, and the appliances used therein—refrigerators, separators, churns and the like.

Section thirteen deals with milk analysis, and in our opinion this might with advantage have been extended. The description of taking the specific gravity by means of a Sprengel tube is, however, a waste of space, as a float or a Westphal balance is always employed in practice.

Again, in estimating the total solids no one would operate on so small a quantity as a gramme, nor are methods depending on the use of asbestos employed in this country.

The methods for the estimation of fat in milk are well and accurately described.

On page 232 the author says, "Salt, cane-sugar, and dextrin are occasionally added to restore the specific gravity lowered by watering." Has the author ever personally come across such instances? The amount of salt required to restore the gravity lowered by watering would surely be so great as to be tasted.

The subject of preservatives, which is now one of extreme importance is dismissed in two and a half pages, and we find no mention whatever of the use of boro-fluorides. We are glad to find on page 243 the author frankly states that preservatives should not be permitted in milk intended for the use of infants, nor (by inference) should they be permitted in milk at all.

(a) "A Clinical Handbook of Urine Analysis." By Charles H. Bedford, D.Sc., M.D. Edin. With illustrations, 10 plates, and three Appendices. Second Edition. Pp. 172. Edinburgh: Bell and Bradburne. 1904.

(a) "Milk: its Productions and Uses. With Chapters on Dairy Farming, the Diseases of Cattle, and on the Hygiene and Control of Supplies." By Edward F. Willoughby, M.D. Lond., D.P.H. Lond. and Camb. Pp. 269, with 65 illustrations. Price, 6s. net. London: Charles Griffin and Co., Ltd.

The last section contains an account of the bacteriology of milk, together with the methods of staining the organisms most likely to be found.

We congratulate the author on the successful way in which he has completed his task of making a readable book, free from padding, but yet containing so much useful information that we predict that a second edition will speedily be required.

#### INTERNATIONAL CLINICS. (a)

The first two volumes of the Fourteenth Series of "International Clinics" are, as regards the subject-matter which they contain, somewhat disappointing. That this must necessarily be the case will be apparent when it is stated that almost every communication, especially in Volume I., appears to have been written, not because the author has something new and important to state, or because he is capable of setting forth the ordinary clinical facts of medicine in a specially attractive form, but because it is wanted as so much copy to help in the making of a book. It would be invidious to single out any individual communications for condemnation, and without doubt it must be at times difficult for the editor to make a selection that will please everybody, but there need be no hesitation in saying that the papers worth reading in the two volumes could easily be contained in one.

Among the best papers in Volume I. are "The Chloride Reduction Treatment of Parenchymatous Nephritis," by Messieurs Vidal and Gaval, and "The Practical Application of Cryoscopy to Medicine," by Dr. Cattell. The former of these is carefully and thoughtfully written, and will well repay perusal, while the latter is an admirable summary of the subject with which it deals. The review of the progress of medical science during 1903 contained in this volume is also excellent.

The first section in Volume II. deals with the diseases of warm climates, and most of the papers in it are fairly good, the best perhaps being those on Hæmoglobinuria and liver abscess. The remaining papers in this volume with the exception of that on Osteomalacia are sketchy and commonplace.

We would like to ask the author of the paper on the "Treatment of Ovarian Lesions," for his evidence of the statement (p. 156, Vol. I.) that "the normal mature Graafian follicle is from 0.5 c.m. to 2.0 c.m. in diameter, and there are in normal ovaries usually eighteen or twenty of these more or less fully developed follicles." Again, on page 62, Vol. II. we presume that it is 30 grains and not 30 grams (*sic*) of quinine Sulphate that are recommended to be taken within four hours.

In contrast to the text, the illustrations in both volumes are of great value, and are splendidly executed. They largely compensate for the other defects that have been noted. The books are nicely bound and printed, and are provided with a good index.

#### REPORT OF THE ARMY MEDICAL DEPARTMENT FOR THE YEAR 1902.

THIS Report possesses more than usual interest in being the first since the cessation of hostilities in South Africa. In view of the public attention which has been drawn to physical deterioration, those parts of the Report which deal with the recruiting of the Army are of special interest. We learn that 307.9 per 1,000 recruits were rejected on inspection, a figure which, compared with the previous year, shows an increase of 26.77. On looking into the causes for rejection, we find that the majority, namely, 4,969, were due to under chest measurement. Loss or decay of teeth follows next with 4,316, while defective vision is responsible for 3,437 rejections. All these numbers are from a total of 87,609 inspected.

We cannot help drawing attention to the Reports on

(a) "International Clinics: A Quarterly of Illustrated Clinical Lectures." Fourteenth Series. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, U.S.A. London: J. B. Lippincott Co. 1904.

surgical operations given in each of the commands, as the classification adopted might certainly be improved. On page 84, we find among the principal surgical operations "one for primary syphilis and one for gonorrhœa."—this leaves much to the imagination as to the exact operation which was performed.

On page 13 it is stated that there were 130 admissions for non-venereal ulcer (the cause of which is not stated) for the United Kingdom, and on page 233, 100 admissions for India, while throughout the Report several other cases are given. From this and from other parts of the Report one would think that non-venereal ulcer of the penis was a common lesion.

In the Report on South Africa we notice that a very frequent cause of invaliding was "caries of teeth," and that this disease alone provided 152 invalids, giving a ratio of 3.35 per 1,000. We are glad to know that steps have at last been taken to look after the teeth in the Army, and surely it would have been more economical to have had these men properly treated in South Africa.

With regard to the sanitary conditions in South Africa some very interesting extracts are given from a Report by Lieut.-Colonel Macpherson, C.M.G., R.A.M.C., on the sanitary conditions likely to affect the health of troops in cantonments and encampments in South Africa. This Report which, has been circulated as an official publication, very clearly brings to notice the backward state of civil sanitation and of sanitary administration in both large and small towns in South Africa, an unsatisfactory state of matters which is probably due, not so much to want of will on the part of the local authorities, as to want of money.

The Indian Report shows that there has been an increase in the number of cases of enteric fever in India, and this increase is attributed to the arrival of large drafts and reliefs from active service in South Africa. There seems to be a special predisposition on the part of the young soldier to acquire enteric during his first year in India, and the very considerable increase in the number of men of the most susceptible age will, to some extent, account for an increase in the actual number of admissions. There were two fatal cases of hydrophobia, and we are glad to learn that during the year the Pasteur Institute at Kasauli, under the charge of Major D. Semple, M.D., R.A.M.C. has continued its good work; 120 patients connected with the British troops in India were treated in the Institute; of these, sixty were bitten by animals proved to have had rabies; eighteen by animals certified by a veterinary surgeon to have had rabies; and forty-two by animals suspected of rabies; not a single one of these cases developed hydrophobia.

It is unfortunate that these valuable Reports should be practically out of date by the time that they are published, but we suppose that it is impossible to avoid their being so.

#### OPPENHEIM'S NERVOUS DISEASES. (a)

PROF. OPPENHEIM'S work is so well known and so highly valued by all neurologists, both on the Continent and at home in its original form, that we feel sure this second edition of the English translation will find many to welcome it. The new matter added to the third German edition has been translated and inserted into this, and the editor has also added the results of research and investigation in the field of neurology since the revision of the German original. Though described on the title-page as a text-book for students and practitioners the work before us differs considerably from what we expect to find in the ordinary text-book, and in these differences lie no inconsiderable part of its charm. The individuality of the author is stamped

(a) "Diseases of the Nervous System: A Text-book for Students and Practitioners of Medicine." By H. Oppenheim, M.D., Professor at the University of Berlin. Translated and edited by Edward E. Mayer, A.M., M.D. Second American edition, revised and enlarged. With 848 illustrations. London: J. B. Lippincott Co. 1904. Price 21s. net.

on every page, and one can well believe his remark that all he has written "is corroborated by personal observation and knowledge."

Our author divides his work into two parts—a general and a special. In the first he treats of the methods of examination, general symptomatology and objective examination; while in the second he treats of the diseases of the cord, the peripheral nerves, the brain, the neuroses, the sympathetic nervous system, and toxic conditions. In dealing with the general examination, Professor Oppenheim mentions only such methods as are likely to be of use clinically. Instruments like aesthesiometers and algesimeters and the "exact measures" used by physiologists are impracticable at the bedside. The electrical examination is very well and fully described, and Erb's figures illustrating the motor points are given, but the use of such figures is greatly lessened by the absence of all anatomical description of their position.

A most interesting feature of the work is the anatomical and physiological description of the nervous system which is prefixed to the sections dealing with the diseases of the spinal cord, peripheral nerves, and the brain. The most recent anatomical investigations of these structures are described and discussed with such clearness and fulness that these sections might be used almost as a text-book on the physiological anatomy of the nervous system. This wealth of anatomical and physiological detail is perhaps the cause of, as it certainly brings more into prominence, the absence of information on the psychological aspect of the nervous system. Professor Oppenheim does deal shortly with hypnotism, and admits it as a valuable therapeutic agent in certain cases; but we miss any suggestion as to the *rationale* of its action or even any criticism of the explanations that have been given of it by others. Surely, however, it is now impossible adequately to discuss the nature of the neuroses or their pathology in the absence of psychological investigation. The study of psychology has, however, been so long neglected by the ordinary medical man that its absence from the work before us will, we believe, be looked upon as an advantage rather than an omission by the majority of its readers. That these readers will be numerous we are fully convinced, and we look forward to seeing the book become one of the standard text-books on neurology among students.

#### HOLT'S CARE AND FEEDING OF CHILDREN. (a)

This is the third edition of a catechism of infant management originally published in America. It is now presented to us in a somewhat enlarged and improved form, with the addition of an introduction from the pen of Dr. Eric Pritchard. The book is intended for the use of mothers and nurses, but in our opinion it is better suited for students of infantile disease and for general practitioners. We have scarcely advanced so far in this country as to entrust the care of infants to nursery maids or even to parents entirely. It is a good thing for medical practitioners that the public are not too skilled in such matters, otherwise some of us might have little enough to do. We fear that a book such as this, if put into the hands of the laity, would to a large extent supplant the family physician. As we have said already, it is more suitable for students and practitioners. The best part of the book is undoubtedly that dealing with the feeding of infants and young children. There is, perhaps, no subject so little understood by the general practitioner as that of infant feeding. Too often artificial foods are ordered regardless of the fact that their usual effect is to produce rickets. Holt has little or nothing to say regarding such foods. In fact, he practically condemns their use when he says (p. 46) that they are "attended with great risk."

(a) "The Care and Feeding of Children." By L. Emmett Holt, M.D., LL.D., Professor of Diseases of Children in the College of Physicians and Surgeons (Columbia University), &c. With an introduction by Eric Pritchard, M.A., M.D., Oxon., M.R.C.P., Lond. Third Edition, revised and enlarged. pp. 149. Price 2s. net. London: Sidney Appleton. 1904.

We understand that this book has met with great success in America, and we have no doubt that physicians in this country will appreciate it quite as much. It gives a very clear outline of the subject with which it deals, and the form of question and answer serves to impress the various facts upon the mind of the reader. In another edition an index might with advantage be added.

#### HAAB'S ATLAS OF EXTERNAL DISEASES OF THE EYE. (a)

This number of the Medical Hand-Atlas Series is a worthy companion to Professor Haab's "Atlas and Epitome of Ophthalmoscopy and Ophthalmoscopic Diagnosis." The fact that it has reached already a second edition proves that it is widely accepted amongst students and general practitioners.

Starting with an excellent chapter on the "Examination of the Eye in Disease" (including a subdivision on the "Detection of Malingerers") the reader is presented with pictures, in print and colours, of the most important external diseases of the eye, beginning with lachrymal diseases and ending with those affecting the orbit. The forty-eight chromo-lithographic plates serve admirably to place before the reader the actual appearance of the various diseases. Each illustration represents a case, the history of which is given in small type on the top of the opposite preceding page—a method worthy of commendation, as it enables one to read the description of the case most readily, while occasionally referring to the illustration for elucidation of the text.

Professor Haab's teaching is broad-minded, and is what one would expect from a man of so great clinical experience, while his editor, Dr. de Schweinitz, does not hesitate to add comments which in several instances present views at variance with those of Dr. Haab.

This form of ophthalmic text-book has much to recommend it from a student's point of view, if the illustrations be well done, as they are in Dr. Haab's books. For it is often a matter of great difficulty to explain to a student by black and white illustrations many of the diseases of the eye, while these difficulties are easily removed by a well-executed coloured illustration.

We can cordially recommend this book to students and general practitioners.

#### THE CASE AGAINST ANTI-VIVISECTION. (b)

In the short and incisive preface prefixed to this little volume, the author tells us that, "The writer of this pamphlet hopes against hope that it will not give grave offence where no offence is intended. Unhappily for him, it is bound to be aggressive. But there is one thing to be said for it, that it keeps close to its subject, which is the methods, literature and arguments of the anti-vivisection societies. It is concerned with them and with nothing else; it puts the case against these societies, and there stops." In discharging the reviewer's task, it is, of course, to us a very patent fact, as well as to every one of our readers, that an elaborate attempt to analyse the garbled statements and limping logic of the anti-vivisectionists can be nothing but a pure waste of time and space. Every medical man, who is in touch with the progress and present status of professional knowledge, knows the principal results obtained by the Vivisectionists; he also knows the principal statements and arguments

(a) "Atlas of the External Diseases of the Eye, including a Brief Treatise on the Pathology and Treatment." By Prof. Dr. O. Haab, of Zurich. Authorised Translation from the German. Second edition, revised. Edited by G. R. de Schweinitz, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, &c. 98 coloured lithographic illustrations in 48 plates. pp. 252. Philadelphia, New York, London: W. B. Saunders and Co. 1903. Price 1s. net.

(b) "The Case Against Anti-Vivisection." By Stephen Paget. 8vo, pp. 104. Price, limp cloth, 1s. 6d. net. London: The Scientific Press, Ltd. 1904.

put forward by the Anti-Vivisectionists. Accordingly had it not been for the continuous endeavour of the latter section of the public to influence our legislators, and prejudice the general public against the most important methods for the advancement of physiological and pathological science, there would be hardly any object in our noticing Mr. Paget's excellent pamphlet. The contents of this are divided into four chapters: I., Anti-Vivisection Societies; II., Literature; III., Arguments; IV., "Our Cause in Parliament." The two latter are, of course, specially deserving of attention at present. The reader who wants to reason his wavering friends out of the fallacies and mis-statements of the Anti-Vivisectionists, should fill his quiver with the weapons provided in the chapter of "Arguments"; and he who is anxious to diminish their future power of legislative mischief should make himself thoroughly acquainted with the last chapter. We cordially congratulate Mr. Paget on the brilliant contribution to the "advancement of science," which we have just read.

#### VENTRE. (a)

THIS volume is so beautifully printed and illustrated that it must secure a certain proportion of attention by these features alone. But it has many other claims. The writer is evidently an enthusiast in the speciality, and has thought it out in all its departments with laborious care and thoroughness. The work of such an author is always deserving of careful scrutiny; it can never fail to illustrate its subject by some new light, even if that light be, in some instances, merely the reflection of the beam, which led the author himself astray. Dr. Bourcart claims for the present work that it is destined to place before the reader, in a scientific point of view, a really new method of treatment "cavertant que procédé exclusif et se suffisant à lui-même, le massage localisé à l'abdomen est de date récente." The author is, very evidently, a past master of his subject, and is prepared to defend his positions with skill and vigour. Nevertheless, it is well to point out that such exclusive statements are peculiarly open to critical aspersion. When the late Sir Henry M. Stanley crossed the "Dark Continent" for the purpose of inflicting "relief" upon Emin Pasha, he was accompanied by a troop of Zanzibaris, mostly as primitive members of the human family as could be found anywhere. We have the testimony of the brave and chivalrous Irish surgeon, Thomas Heath Parke, who was the medical officer of that expedition, to the fact that when one of those dark-complexioned natives became afflicted with abdominal twinges, his favourite procedure was—when collateral circumstances proved non-conflicting—to place himself on the ground, in the supine posture and horizontal plane, and there and then have his abdomen "walked on" by one of his (barefooted) compatriots. And very effective was this pre-scientific mode of applying localised abdominal massage reported to be! And we may be pretty sure that directly after the eviction of our common ancestor from the Garden of Eden and the beginning of his liability to the ills of the flesh, he practised massage when his great toe abruptly collided with an unexpected fragment of rock, or his shin with a fallen tree. And when the abdominal surface received the impact of a foreign body with a very unusual amount of *vis viva*, we feel pretty certain that the good offices of Eve were requisitioned for the purpose of diminishing by pressure and friction the personal inconveniences to which her curiosity and disobedience had rendered her fallen spouse liable. That massage is the most primitive weapon in the surgical armamentarium we have no doubt whatever. But it is only of recent years that its application has been reduced to approximate scientific order. Our author tells us in his preface that, "C'est par le développement scientifique du massage gynécologique que le

*massage scientifique du ventre s'est créé*," and he promptly adds that "c'est par les travaux des premiers pionniers de langue française qui se sont rendus à Stockholm (Jentzer et moi d'abord; puis Stapfer et d'autres encore) que l'élan a été donné." The sketch of the surface anatomy of the abdomen is a good one, and copiously illustrated—after the Paris "Salon" style; the account of the internal anatomy is also good, and very clearly put—as French word painting usually is. The directions for renal massage are excellent, and the accompanying illustrations are worthy of all praise.

#### THE NATURE OF MAN. (a)

DR. MITCHELL, in presenting this work to English readers claims that Metchnikoff "has gained the right to a hearing by forty years of patient devotion and brilliant research. In the volume now given to the public he has addressed himself to the gravest and most serious problems of humanity, to life and sex and death and the fear of death." And the somewhat startling statement is made that "now for the first time in the history of thought, the exact methods of science have been brought to the statement of these problems."

The work is certainly a remarkable one, and not without danger in its fascination, but nevertheless rich in suggestiveness and stimulating to serious thought. Metchnikoff has well won a high reputation as a biologist, but pathologists know that he has also some of the elements which go to make a great romancer. The contents of the present volume are perhaps best considered as the products of the recreative hours of an ageing naturalist desirous of contributing something to the conceptions of human existence before the curtain is rung down on the individual observing life.

The author has turned aside from the day's pursuit to wander into regions which the lamp of science will probably never enlighten. He attempts to dabble in the deep waters of faith and tries to sound the depths of religious belief with the short line plummet allowed by science. The result is oftentimes disappointing, and Metchnikoff in these pages has done himself grave injustice by departing from the position of a reverent agnostic and assuming a dogmatism which is lacking in scientific spirit and indecorous to certain of the dearest beliefs and desires of the keenest thinkers.

We fear the enigmas of life and death are not to be revealed by such brilliant but misleading presentations as are contained in these pages.

The volume is divided into three sections, and deals respectively with the disharmonies in the nature of man; attempts to diminish the ills arising from the disharmonies of the human constitution (religious and philosophical systems); and what science is able to do to alleviate these disharmonies.

We cannot attempt to survey the many features of this striking work, for every chapter affords material for careful consideration, and is capable of initiating endless discussion. The many references will prove invaluable to students and no one can read these pages without being impressed by the importance of the subjects raised. It is, however, a work which needs to be read with wise discernment, and is hardly a volume to be placed thoughtlessly in the hands of untrained laymen. The insistence on the view that disharmonies in the human constitution are the chief sources of our sorrows may serve to solve some of the problems of human existence, but we fear the doctrines set forth in this book, ingenious and peculiarly fascinating as many of them are, will hardly lighten the burden which many have to carry, or serve as directing light along life's dark pathway.

(a) "Le Ventre: Etude Anatomique et Clinique de la Cavité Abdominale au point de vue du Massage. I. Le Rein." Par Dr. M. Bourcart. Ouvrage illustré de 184 figures. Genève: H. Kundig, Editeur. Paris: F. Alcan, Editeur. 1904.

(a) "The Nature of Man: Studies in Optimistic Philosophy." By Elite Metchnikoff, Professor at the Pasteur Institute. The English translation edited by P. Chalmers Mitchell, M.A., D.Sc. (Oxon.), Secretary of the Zoological Society of London. Pp. 288. 20 Figs. London: William Heinemann, 1903. Price 12s. 6d.

## Literary Notes and Gossip.

"LEMCO Dishes for all Seasons," issued by the Leibig's Extract of Meat Co., is not only a useful and artistic advertisement of the manifold advantages of the preparation they are pleased to call by the fanciful and euphonious name of "Lemco," but is an ingeniously arranged and thoroughly serviceable cookery book which we commend to the consideration of nurses and those who may be called upon to prepare appetising dishes for the sick and delicate.

THE forthcoming number of the *British Journal of Inebriety*, the official publication of the Society for the Study of Inebriety, will contain an important article on "The Criminal Responsibility of the Alcoholic," by Dr. W. C. Sullivan, and also a criticism by Dr. Harry Campbell on certain recently promulgated views on the pathology of chronic alcoholism.

THE August number of the *Journal of the American Medical Association* contains a special article on the History of the United States Public Health and Marine Hospital Service. A well-merited tribute of praise is given to Surgeon-General Wyman, who by his admirable foresight and diplomacy saved the country in 1892 from the threatened cholera invasion. The same officer has been mainly responsible for the expansion and centralisation of public health work in America, and was also one of the first to suggest a plan for international sanitation of sea-ports. Among the "original articles" is one on "Static Foot Error," by W. P. Blodgett, M.D. The incidence of these troubles is tabulated according to sex, age, time of year, occupation and etiology. Pain in the ankle region is said to be the most common symptom, and it is pointed out that while relief is usually obtained by the use of suitable spring supports, it is only in very few cases that such supports can ever afterwards be dispensed with. In a paper entitled "Practical Notes on Ointments: their Use and Abuse," Dr. Duncan Bulkley points out the principal indications for the use of ointments, and also gives some practical hints on the way to compound them. Dr. V. A. Latham reports on a case of "Neoplasm of the Pulp," which he regards as a carcinoma. He considers his case important with reference to the site of origin of tongue and gum cancers.

THE July "Bulletin" of the Johns Hopkins Hospital, Baltimore, contains (1) "The Sensory Distribution of the Fifth Cranial Nerve," by Harvey Cushing, M.D. In this most valuable article Dr. Cushing gives us the results which he has obtained by a careful examination of the area of anaesthesia left in patients by destruction or avulsion of the sensory root of the fifth nerve. In all twenty-six cases were examined, and the examination was made in most of them shortly after the operation. The area of anaesthesia mapped out corresponds closely with that figured by Frohse, as the results of his anatomical studies. Posteriorly it includes a portion of the helix of the auricle, and also the anterior wall of the external auditory meatus. This is what would be expected from a study of the development of these parts, inasmuch as these portions of the ear are developed from the mandibular arch. Cushing also points out the important fact that the skin areas supplied by the different branches of the fifth nerve do not overlap. (2) "Stephen Hales, the Physiologist," by Percy M. Dawson, M.D. This is an interesting historical sketch dealing chiefly with the physiological experiments of Hales. (3) "The Chemical Origin of Leucocytes," by E. Schnoll, M.D. The object of this elaborate research was to answer the question "Is the adult human body capable of synthesising nucleins from nuclein free food, or is it dependent for its nucleins upon those ingested in the food?" To answer this Schnoll investigated the blood in leukaemic cases. While feeding these cases on (a) ordinary diet, (b) purin-free, albumin rich diet (c) mixed purin-albumin rich diet, (d) purin rich and

albumin rich diet, he found that the number of leucocytes increased in the blood with increase of albuminous diet, irrespective, apparently, of the nuclein contents. His observations are too few, as yet, for a definite conclusion, but so far he is led to believe that nucleins can be manufactured in the adult body. (4) "Mental Phenomena and Visceral Disease," by Carey B. Gamble, jun., M.D. In the proceedings of the Hospital Medical Society Dr. Painter read an interesting communication on the "Pathology of Rheumatoid Diseases," and a case of tuberculosis of the parotid gland was exhibited by Professor Osler.

OUR youthful contemporary, the *South African Medical Record*, a monthly journal devoted to the interests of the medical profession in South Africa, has for the most interesting paper in the August number one by Dr. P. D. Strachan, entitled "The Question of the Presence in South Africa of Undulant or Malta Fever." In it he points out that a number of cases of fever are met with in South Africa which, although usually called typhoid fever, bear a most close resemblance clinically to Malta fever. That they are not malarial in origin is proved by the examination of the blood, and by the inefficiency of quinine in treatment. Up to this Dr. Strachan has been unable to make use of bacteriological methods of diagnosis, but he hopes to do so shortly, and will make known his results. The question of medical advertising is dealt with in a strongly worded editorial. Advertisements of medical men, both direct and indirect, had become so common that recently the Cape Medical Council was compelled to endeavour to put a check to it by dealing severely with all cases that came under its notice. This has led in some cases to hardship, and, in consequence, there has been some outcry against its decrees. We are glad, however, to see that the Council is determined to uphold the position that it has taken up, and will in future enforce fully its decrees. As an example of a common (indirect?) method of advertisement, and one of a peculiarly objectionable type, we may quote the following, which appeared in the *Cape Times* of April 19th: "I hereby tender my sincere thanks to Dr. Wood, Dr. Pringle, and Dr. Drew, also to the Sister of the Brickersteth Ward, New Somerset Hospital, for the kindness and attendance to me during my stay at the hospital."

THE 60th Annual Report of the British Medical Benevolent Fund, for the year 1903 has just been issued and should be studied by all who are in any way able, either by sympathy or financial support, to assist in the relief of distressed qualified members of the profession, their widows and orphans. This excellent work deserves the highest praise and most unqualified approval and practical encouragement.

### NEW BOOKS AND NEW EDITIONS.

THE following have been received since the publication of our last list:—

- ADLARD AND SONS (London).  
Asthma in Relation to the Nose. By Alexander Francis, M.B., B.C. Cantab. Pp. 136. Price 3s. net.
- BAILLIERE, TINDALL AND COX (London).  
Adenoids. By Wyatt Wingrave, M.D. (Medical Monograph Series, No. 9.) Illustrated. Pp. 128. Price 2s. 6d. net.
- A Manual of Practical Medical Electricity. By Dawson Turner, B.A., M.D., &c. Fourth Edition, revised and enlarged. Illustrated. Pp. 433. Price 10s. 6d. net.
- Diseases of the Stomach and their Surgical Treatment. By A. W. Mayo Robson, F.R.C.S., and B. C. A. Moynihan, M.S. Lond., F.R.C.S. Second Edition. Illustrated. Pp. 508. Price 15s. net.
- Railway and Other Accidents with Relation to Injury and Diseases of the Nervous System. A Book for Court Use. By Allan W. Lane Hamilton, M.D., F.R.S.E. Illustrated. Pp. 351. Price 15s. net.
- The Cancer Problem in a Nutshell. By Robert Bell, M.D., F.F.P.S., &c. Pp. 39. Price 1s. net.
- Practical Chemistry, including Simple Volumetric Analysis and Toxicology. By P. A. Ellis Richards, F.I.C. Pp. 136. Price 3s. net.
- JOHN BALE, SONS AND DANIELSSON (London).  
Adenoid Growths of the Naso-Pharynx. Diagnosis, Symptoms, and Treatment. By G. A. Garry Simpson, M.R.C.S. Eng. Illustrated. Pp. 43. Price 3s. 6d.
- CASSELL AND CO., LTD. (London).  
Serums, Vaccines, and Toxins in Treatment and Diagnosis. By Wm. Cecil Bosanquet, M.A., M.D. Pp. 344. Price 7s. 6d.

- The Student's Handbook of Surgical Operations. By Sir Frederick Treves, Bart., K.C.V.O., C.B., LL.D., F.R.C.S. New Edition, revised by the Author and Jonathan Hutchinson, [jun.], F.R.C.S. Illustrated. Pp. 486. Price 7s. 6d.
- J. & A. CHURCHILL (London).
- Beri-Beri: its Symptoms and Symptomatic Treatment. An Essay by Percy Netterville Gerrard, B.A., M.D., &c., &c. Pp. 95. Price 2s. 6d. net.
- Clinical Diagnostic Bacteriology. By Alfred C. Coles, M.D., D.Sc., F.R.S. Edin., with coloured plates. Pp. 237. Price 8s. net.
- The Development and Anatomy of the Prostate Gland. By W. G. Richardson, M.B., B.S., &c. Pp. 121. Price 10s. 6d. net.
- The Examination of Waters and Water Supplies. By John C. Thresh, D.Sc., M.D., D.P.H. Pp. 460. Price 14s. net.
- ARTHUR C. FIFIELD (London).
- The Ballad of Judas Iscariot. By Robert Buchanan. Pp. 21. Price 3d.
- Selections from Tennyson's "In Memoriam." Pp. 39. Price 3d.
- Culture. By Ralph Waldo Emerson. Pp. 38. Price 3d.
- Walkden; My Life in the Woods. By H. D. Thoreau. Pp. 158. Price 6d. net.
- Master and Man. By Leo Tolstoy. Pp. 96. Price 6d. net.
- Tolstoy as a Schoolmaster. By Ernest Crosby. Pp. 94. Price 6d. net.
- H. K. LEWIS (London).
- Enlargement of the Prostate. its Treatment and Radical Cure. By C. Mansell Moullin, M.D. Oxon., F.R.C.S. Third Edition. Pp. 204. Price 6s.
- J. B. LIPPINCOTT Co. (London).
- International Clinics. Vol. II. Fourteenth Series, 1904. Edited by A. O. J. Kelly, A.M., M.D. Philadelphia, U.S.A. Pp. 314.
- LONGMANS, GREEN AND Co (London).
- Elementary Practical Physiology. By John Thornton, M.A. Illustrated. Pp. 324. Price 3s. 6d.
- MACMILLAN AND Co., LTD. (London).
- The Story of an East London Hospital. Pp. 92. Price 2s. 6d. net.
- JOHN MURRAY (London).
- Handbook of Physiology. By W. D. Halliburton, M.D., F.R.S. Sixth Edition. Illustrated. Pp. 902. Price 13s. net.
- REEMAN, LIMITED (London).
- An Atlas of Human Anatomy. By Carl Toldt, M.D., assisted by Prof. A. D. Rosa, M.D. Translated by M. Eden Paul, M.D. Brux. Fifth Section, F. Angiology. Pp. 742. Price 13s. 6d. net.
- THE SCIENTIFIC PRESS, LTD. (London).
- The Pocket-Book of Temperature Charts. Price 6d. net.
- SMITH, ELDER AND Co. (London).
- An Index of Symptoms as a Clue to Diagnosis. By Ralph Winnington Lettwich, M.D. Third Edition. Pp. 399. Price 6s. net.
- YOUNG J. PENTLAND (Edinburgh).
- The Nervous Affections of the Heart. By George Alexander Gibson, M.D., D.Sc., &c. Illustrated. Pp. 99.

## Obituary.

### PROFESSOR NIELS FINSEN, OF COPENHAGEN.

THE death of Professor Finsen, at Copenhagen, on the 24th instant, has excited world-wide regret. Although he had attained the age of 43 only, his name had nevertheless become familiar in all civilised countries by reason of his famous discovery of the "light cure" for lupus. For years past his health had been precarious, so much so, indeed, that he had been unable to take an active part in the development of his original discovery. The great merit of his work was that which must always remain attached to the man who takes the first step on a new pathway of human knowledge and achievement. Finsen's name will be ever associated with the ultra-violet treatment of lupus and of other skin diseases. The ultra-violet rays occur naturally in sunlight, and may be obtained artificially by an electric arc light. Both methods were used by Finsen in his apparatus, and were shown by him to have a special action on the skin of man as well as a bactericidal effect on micro-organisms. In applying these rays he showed that they possess far greater power of penetration in bloodless tissues than in those filled with blood. In the original apparatus the light from a powerful arc lamp was led through a tube so arranged as to concentrate the violet and ultra-violet rays and to remove the heat rays. To effect this, water was kept running between quartz lenses. One of the latter pressed on a lupus for an hour or more daily for many months was found to cure the disease in almost all cases. The apparatus was costly and the course tedious, and Finsen's method has undergone numerous modifications in the direction of quickness, cheapness, and ease and convenience of application. It may be questioned whether, on the whole, ordinary surgical measures are not preferable in the treatment of lupus. Finsen, however, opened up to the medical world a fresh field of therapeutics, whose fruits may be some day both multitudinous and fair. In our own country the

Finsen light cure of lupus has been known chiefly in connection with the London Hospital. It was introduced there by Queen Alexandra, who furnished the necessary installation entirely at her own expense. Her Majesty, accompanied by her sister, the Dowager Empress of Russia, had become acquainted with the wonders of the new treatment at a visit to Professor Finsen's Medicinske Lysinstitut in Copenhagen, in April, 1899. Immediately on her return home Queen Alexandra communicated with the London Hospital. Shortly afterwards Dr.—now Sir—Stephen Mackenzie visited Copenhagen to study Finsen's methods, and later a matron and a nurse from the London Hospital followed for the same purpose. Not content with providing the means alone, we understand that Her Majesty sent the first patient in the person of a poor girl from Great Footers, near Egham. The Queen has followed the subsequent progress of the Finsen treatment at the London Hospital with the greatest interest and has paid frequent visits of inspection to that institution. The example of Dr. Finsen, who constituted to compass so much good work in a life so frail and brief, may well be held up as a pattern to all members of his humane and self-sacrificing profession.

### DR. CROKER, BELFAST.

THE death occurred last week, on the 22nd inst. of Dr. George Croker, one of the oldest practitioners in Belfast. If he had lived six weeks longer, he would have entered on his 90th year, having been born on October 31st, 1815, in Beaufield House, Co. Wicklow. He was for some years family physician to the Marquis of Downshire, and then surgeon to the Royal South Down Rifles at Hillsbro'. When the headquarters of the regiment was removed to Downpatrick, he retired from that post, and was appointed to a dispensary on the east side of Belfast, where he continued to practise till failing health obliged him to resign six years ago. To the present generation of medical men in Belfast, Dr. Croker was known as a most genial and kindly old gentleman, of the highest principles and old-world courtesy. His ruling passion was a love for animals of all sorts.

### DONALD FLUDYER BOULTON, M.R.C.S. ENG. L.S.A.

It is with regret that we have to record the death of Dr. Donald Fludyer Boulton, at his residence Newmarket Street, Usk, on the 11th instant. The deceased gentleman, who was 62 years of age, had a paralytic stroke three weeks ago. Dr. Boulton succeeded his father as surgeon at H.M. Prison, Usk about thirty years ago, was club doctor to two or three Friendly Societies in the town, and had an extensive practice. Dr. Boulton was a most enthusiastic sportsman, and was a keen follower of the Llangibby Hounds, and was often with the otter hounds. In his younger days he was a gentleman jockey, and rode winners at the local races. He was very popular and highly respected in the district generally. He was educated at St. Bartholomew's, and took the qualifications of membership of the R.C.S. and the L.S.A.

### THOMAS CHAPLIN, M.D. ST. AND., &c.

DR. THOMAS CHAPLIN, formerly of Jerusalem and afterwards of St. Leonards, died last week at his residence, St. Leonards, in his seventy-fourth year. Professionally educated at Guy's Hospital, he was admitted a member of the Royal College of Surgeons, England, and a licentiate of the Society of Apothecaries in 1853, and took the M.D. Degree at St. Andrews in 1858. He was formerly resident in Jerusalem where he was physician to the English Mission Hospital for Jews, honorary physician to the German Hospital and Leper Asylum, and President of the Jerusalem Medical Society. Dr. Chaplin, who was a honorary Associate of the Order of St. John of Jerusalem, was a member of the Council of the Victoria Institute and of the Executive Committee of the Palestine Exploration Fund. He had written, amongst other subjects,

on the "Fevers of Jerusalem," and for the Victoria Institute on "Some Diseases Mentioned in the Bible."

## Medical News.

### The Midwives Act.

WE are requested to publish the following resolution adopted by the Council of the Incorporated Medical Practitioners' Association:—"That we, the Council of the Incorporated Medical Practitioners' Association, at this our first meeting since the vacation, desire to place on record our protest against the action of the Central Midwives Board in deciding to appoint as examiners for the certificate of the Board non-medical women, thereby raising, to the level of the duly registered medical practitioner who has undergone an expensive course of study and a searching examination, women who are not required to show proof that they possess any knowledge of the different subjects which a medical practitioner has to study in order to obtain a diploma."

### Ankylostomiasis.

A COMMITTEE representing the South and West Yorkshire coalowners and the Yorkshire Miners' Association is engaged in devising measures to prevent the introduction of ankylostomiasis into the pits in Yorkshire. Among other steps it is intended to give lantern-illustrated lectures at the various mining centres, in order to secure the intelligent co-operation of the men. The two lecturers appointed are Dr. Porter of Sheffield and Dr. Vaughan Bateson of Bradford, the task of illustration being entrusted to Mr. Scott, the Secretary of the Committee.

### Carbolic Acid Poisoning.

MR. WALTER SCHROEDER, Deputy-Coroner for the Central District of London, stated, at an inquest at Hampstead recently, that since the Order in Council declaring that liquid preparations of carbolic acid and its homologues, containing more than 3 per cent. of those substances, are to be deemed poisons, the number of deaths, accidental or suicidal, from this cause has very greatly decreased. It will be remembered that it was largely owing to the exertions of the British Medical Association that the Order in Council was issued.

### Sir William MacGregor.

A DINNER was given on September 16th by Sir Alfred Jones, President of the Liverpool Chamber of Commerce, in honour of Sir William MacGregor, K.C.M.G., C.B., late Governor of Lagos, who has been appointed to the Governorship of Newfoundland. A sum of nearly £1,000 was subscribed by those present to be handed over to the Liverpool School of Medicine in the name of Sir William MacGregor in recognition of his services to sanitation in West Africa. Sir William MacGregor is a Doctor of Medicine of the University of Aberdeen.

### A Chemical and Pharmaceutical Congress.

A CONGRESS of Chemistry and Pharmacy organised under the auspices of the Pharmaceutical Association of Liège and the Chemical Society of Belgium, will be held in connection with the International Exposition to be held at Liège in July, 1905. In addition to technical matters, questions relating to legislation and professional ethics will be discussed. Communications should be addressed to one of the Secretaries, M. J. Raymond, 16, Place des Carmes, Liège, or M. J. Wauters, 83, Rue Souveraine, Brussels.

### West London Medico-Chirurgical Society.

THE following are the officers and members of Council for 1904-5:—President: Mr. C. M. Tuke.\* Vice-Presidents: Mr. C. B. Keetley, Mr. W. P. Barrett, Dr. G. H. D. Robinson, Mr. J. R. Lunn, Dr. E. Furniss Potter, Dr. E. Bromet,\* Dr. G. P. Shuter,\* Mr. H. Webb.\* Council: Mr. R. Pollock, Dr. A. M. Ross Sinclair, Mr. G. A. Garry Simpson, Dr. Percy Dunn, Mr. McAdam Eccles, Mr. E. P. Paton, Dr. A. Saunders, Dr. A. J. Rice Oxley, Dr. J. A. Mansell Moullin,\* D.

A. Morison,\* Dr. A. E. Russell,\* Dr. C. Buttar,\* Treasurer: Mr. T. Gunton Alderton. Secretaries: Dr. Andrew Elliot, Dr. W. H. Walter.\* Librarian: Mr. H. W. Chambers. Editor of Journal: Dr. Leonard Dobson. Editorial Secretary: Mr. J. G. Pardoe. (Those marked with an asterisk did not hold similar office last year.)

The evening meeting will be held at the West London Hospital on Friday, October 7th, at 8.30 p.m. The President, Mr. C. M. Tuke, will deliver an address on "Progress in Psychology."

### Requests to Medical Charities.

By the will of Mr. Thomas Whiffin, of Putney, who died on March 27th, the following bequests are directed to be paid, free of legacy duty:—£500 each to St. George's Hospital, St. Thomas's Hospital, Guy's Hospital, Charing Cross Hospital, the Metropolitan Free Hospital, Kingsland Road, King's College Hospital, the Middlesex Hospital, and the Victoria Hospital for Children, Queen's Road, Chelsea; £250 each to the Brompton Hospital for Consumption, the National Hospital for Paralysis and Epilepsy, Queen's Square, Bloomsbury, the Hospital for Women, Soho Square, the Samaritan Free Hospital, Marylebone Road, the City Orthopaedic Hospital, Hatton Garden, the Central London Ophthalmic Hospital, the Royal Hospital for Incurables, Putney, the Asylum for Idiots, Earlswood; the Royal Blind Pension Society, and the Royal Association in Aid of the Deaf and Dumb, Oxford Street.

### The British Gynaecological Society.

THE annual dinner of this Society will be held on Thursday, November 24th, at the Monico, Piccadilly Circus, at 7.30 p.m.

### The Royal Academy of Medicine in Ireland.

THE annual general meeting of the Royal Academy of Medicine in Ireland will be held on Friday, October 14th, at 4.30 p.m., at the Royal College of Physicians, Kildare Street, when the report will be submitted and the election of officers will take place.

## OPERATIONS.—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), St. Ormond Street (9.30 a.m.), St. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (2.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Centre (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES or LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

### A WARNING.

OUR London readers should note that just at present the police are making active inquiries as to the whereabouts of a tall young man with a scar on his forehead, who is stealing things from consulting and waiting rooms. His plan is to call outside consulting hours and ask to be allowed to write a note for the medical man on his return.

**DR. T. (Lewisham).**—Speaking generally, one year's hospital training is absolutely inadequate to turn out a properly equipped nurse. Three years at least is necessary, and a still further experience of hospital life is requisite if she aspires to taking any of the posts including supervision in the larger institutions for the sick. It is just possible here and there that an individual case may demand exceptional treatment, as, for instance, when a nurse received her training in the days when a three years' course was not considered essential. It would be impossible, however, to give an opinion on any such instance without a full acquaintance with the facts of the case.

**THE DIMINISHING BIRTH-RATE.**—It is a fact that the Society of Medical Officers of Health were unable to come to a decision as to whether or not the declining birth-rate of the United Kingdom was due to "preventive" practice amongst married persons.

**F. B. C. S. (Birmingham)** writes us asking if any of our readers have known cases where gall-stones have been vomited. He has recently had under his care a patient who nearly died from exhaustion, &c. There was localised peritonitis and symptoms pointing to impacted gall-stone. She refused operation, but recovered ultimately after vomiting a large gall-stone. (For similar case see Jonathan Hutchinson's "Smaller Atlas of Clinical Illustrations," Plate lvii.—Ed. M.P. & C.)

**BRISTOLIENSIS.**—Diabetes insipidus has been met with occasionally in Raynaud's disease, and glycosuria more frequently, and in some instances the sugar appeared to be secondary to gangrene. Raynaud recorded an interesting case in the *Nouveau Dictionnaire*, 1872, in which he gave the probable sequence of events as several years of recurring local asphyxia, then diabetes, which brought on gangrene and tuberculosis. One of the best comprehensive accounts of Raynaud's disease with which we are acquainted is to be found in Munro's book, published in 1899 by Maclehoose and Sons, of Glasgow.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, SEPTEMBER 28th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (23 Chenies Street, W.C.).—4 p.m. Mr. T. P. Legge: Clinique. (Surgical.)

THURSDAY, SEPTEMBER 29th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (23 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY, SEPTEMBER 30th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (23 Chenies Street, W.C.).—4 p.m. Mr. R. Lake: Clinique. (Ear.)

## Vacancies.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per

annum, with board, apartments and washing. Applications to the Secretary, the Infirmary, Leicester.

West Riding of the County of York—Storthes Hall Asylum Kirkstall, near Huddersfield.—Assistant Medical Officer. Salary £140 per annum, with furnished rooms, board, attendance, and washing. Applications to the Medical Superintendent.

French Hospital and Dispensary, 172 Shaftesbury Avenue, W.C.—Resident Medical Officer. Salary £80 per annum with full board. Applications to the Secretary.

Ancoats Hospital, Manchester.—Resident House Physician. Salary £80 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

The Manchester Northern (late Clinical) Hospital for Women and Children.—House Surgeon. Salary £80 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38 Barton Arcade, Manchester.

Central London Throat and Ear Hospital, Gray's Inn Road.—Second Assistant Anaesthetist. Honorary yearly appointment. Applications to be made before September 28th to Richard Kerhan, Secretary.

Royal Halifax Infirmary.—Third House Surgeon. Salary £80 per annum, with residence, board, and washing. Applications to Oates Williams, Secretary, Royal Halifax Infirmary, Halifax.

Northampton General Hospital.—House Surgeon. Salary £100 per annum, with furnished apartments, board, attendance, and washing. Applications to C. S. Biebee, Secretary-Superintendent.

Newcastle-upon-Tyne City Hospital for Infectious Diseases.—Resident Medical Officer. Salary £100 per annum, with board, lodging, &c. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

The Earlswood Asylum, Redhill (The National Training Home for the Feeble-minded).—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, washing, &c. Applications to the Secretary, 36 King William Street, London Bridge, E.C.

Parish of Kensington.—Second Assistant Resident Medical Officer. Salary £80 per annum, with apartments, board, and washing. Applications to W. H. Stephens, Clerk to the Guardians, Marlow Road, Kensington, W.

## Appointments.

FELTON, WALTER B., L.R.C.P.L., L.R.C.S.I., Medical Officer and Public Vaccinator for the Newlyn East District by the St. Columb (Cornwall) Board of Guardians.

JOHNSON, W. CROSBY, M.B., Ch.B. (Vic), Honorary Physician to the Pendleton Branch Dispensary of Salford Royal Hospital.

RODGER, T. E., M.B., B.S. (Glasg.), Certifying Surgeon under the Factory Act for the Salford District of the County of Dumfries.

SIMPSON, THOMAS YOUNG, M.R.C.S., L.R.C.P. (Lond.), Junior House Surgeon at the Royal Albert Hospital, Devonport.

STYLL, F. W., M.R.C.S., L.R.C.P. (Lond.), Medical Officer for the Brest (Devon) and District Postal Staff.

## Births.

CHANCE.—On September 20th, at 90 Merrion Square, W., the wife of Arthur Chance, of a son.

## Marriages.

BOURNE—ROBERTS.—On September 21st, at Holy Trinity, Sittingbourne, Kent, Henry James Frederick Bourne, L.R.C.S., L.R.C.P., of Bridge House, Halling, Kent, eldest surviving son of the late Henry Bourne, of Antigua, W.I., and Redhill, Surrey, to Lillian Theodora, youngest daughter of the late Rev. W. Roberts, formerly vicar of Halling, Kent.

CARR—MORRIS.—On September 21st, at Shanghai Cathedral, Sydney H. Carr, M.D., son of the late T. W. Carr, of Newtown House, Carlisle, Cumberland, to S. Emmie Morris, Ovoca, Elliot Hill, Lewisham, London.

DALTON—BRINSLEY SHERIDAN.—On September 20th, at the Cathedral, Mullingar, by the Rev. R. A. O'Reilly, S.J., Clongowood (uncle to the bride), assisted by Rev. W. Egan, P.P., Mount Nugent; Rev. L. J. Condon, O.S.A., and Rev. Michael M'Sweeney, Cork, Richard Dalton, Esq., M.D., son of Garret Dalton, Esq., 68 Grand Parade, Cork, to Roseamond, youngest daughter of Richard Brinsley Sheridan, Esq., J.P., Lake View, Mount Nugent, co. Cavan. No cards.

STOCK—VAN BEEK.—On September 20th, at St. Peter's Cathedral, Pietermaritzburg, Natal, Phillip Graham Stock, Captain R.A.M.C., Assistant Medical Officer of Health, Johannesburg, youngest son of Granger Stock, Clifton, Bristol, to Ellen Elizabeth (Nellie), eldest daughter of Carl Van Beek, Esq., Johannesburg.

## Deaths.

ASHTON.—September 19th, at Marlborough Lawn, Cheltenham, Brigade Surgeon William Ashton, eldest son of the late William Ashton, Esq., of Donerail, co. Cork, aged 68.

CLARKE.—On September 20th, at 23 Lower Look Gardens, Brighton, Margaret Beatrice, widow of Vans Christian Clarke, M.D., B.N., aged 82.

FOSTER.—On September 21st, Mary Bound, the wife of Joseph Foster, M.D., of 10 St. George's Road, Eccleston Square, aged 61 years.

### THE ISOLATION HOSPITAL.

By G. D. MARRIOTT, L.R.C.P., L.F.P.S. Glasg.,  
Medical Officer of Health, Borough of Nottingham.

THE isolation hospital is a preventive institution or nothing. If it fails to prevent it fails altogether. To imagine that it could remain as a nursing-home is to misapprehend the aim and object of such undertakings, and to lose sight of the financial considerations which are involved. The main purpose which they were intended to serve and the chief use to which they have been put was the aggregation of cases of scarlet fever. Attention has at last been compelled to the fact that the system cannot be justified in the face of notification returns, and we are now being asked to believe that such places are at least necessary for the better nursing of enteric and other cases. In other words, the isolation hospital, having failed as a means of prevention, is to survive as a pauperising institution—a state of things which would be as impossible as it would be absurd.

It has been said that the wholesale condemnation of the isolation hospital was at least a tactical blunder, that it would have been wiser to advocate the limitation of the scope of the proposed inquiry to scarlet fever isolation. But would it be possible to so limit it? I doubt it. It would be difficult, for instance, for a Royal or other Commission to exclude from its deliberations discussions dealing with the "isolation" of diphtheria and those borderland variants to which Dr. Biss has so ably called attention. Should it be proved, as we believe it will be, that "isolation" in both cases has been a gruesome mistake, there will be such an outcry in this country as will enforce a further inquiry into the consequences, both to the individual and the community, of the aggregation system generally. In my judgment such an inquiry, carried out from an authority from which, as Dr. Millard rightly suggests, all partisans should be excluded, could only end in one way—namely, in the complete abolition of a system which never had a ray of sanction either of science, experience, or common sense.

Let it be granted, for the sake of argument, that the result of the inquiry is a general condemnation, so far as the "isolation" of scarlet fever and diphtheria are concerned; what work, then, remains for the isolation hospital to do?

Thanks to sanitary betterment—and not to the aggregative system—we have got rid of

relapsing fever. If typhus has not yet entirely disappeared, it is because of the neglect of the most elementary precautions against a disease the *materies morbi* of which is not able to cross an open space. Enteric cases are successfully nursed in the common wards of general hospitals. Measles and whooping-cough, it is generally conceded, will never be made the subjects of experimental "isolation," as has been the case with scarlet fever. This leaves us only small-pox to deal with. I wish here to be as guarded as I always have been in my criticism of the small-pox hospital—an institution which is generally dissociated, as far as possible, from the ordinary isolation hospital. That the aggregation of small-pox cases is bad for the aggregated I never had any doubt. In the case of a disease the striking-distance of which is so great, removal in presence of the usual crowd must be regarded with suspicion, and is a fact which few would attempt to deny. Nor can the constant presence of the small-pox cab in the crowded thoroughfares of a city be looked upon with any degree of satisfaction. True it is also that the removal of the first case does not always—it would be correct, probably, to say does not often—prevent the spread of the disease either in the home or in the locality. The safeguard here, as we all know, is vaccination. In vaccination we have a means of prevention which transcends in importance every system of "isolation" that has ever been devised, and without which no system could succeed at all. It is surely, then, more reasonable, and more scientific, to insist on the passing of a Re-vaccination Bill than to advocate the covering of the earth with small-pox hospitals. In this connection it will not have escaped the notice of the profession that the medical officer of health of this city has been recently successfully treating small-pox cases in what was practically the open air—cases which he despaired of getting well if left in the wards of the small-pox hospital. Dr. Bobbyer's reading of these happenings may not chime with mine; probably it does not, but the fact is generally interesting, and to me significant.

Since the passing of the Public Health Bill almost the sole conception of disease-prevention has been the erection and crowding of so-called up-to-date and well-equipped "isolation" hospitals. Monies that ought to have been devoted to works of sanitation, which is to say disease-prevention, have been squandered on experimentation. In spite of the generally recognised impossibility of obtaining any data on which such a claim could be based, medical

politicians, such as Sir Walter Foster, have been declaring that, but for such institutions the population of these islands would have been long ere this decimated and our civilisation destroyed; and lamenting that the whole municipal debt of three hundred millions had not been incurred in the establishment of isolation hospitals. While leading politicians who are members of our profession talk like this, can it be wondered at that others in less exalted positions have persuaded themselves that they can settle these important questions with a wave of the hand, or that an enlightened, though not converted, section of the medical press should give such grudging assent to what it is no longer able to ignore?

Now one word of warning. It is probable that the value of the "isolation" hospital is now about to be appraised. Let us hasten slowly! It is inconceivable that any greater mistake could be made than to hurry the thing forward. The question is ripe for discussion among ourselves—it is not yet ripe for an inquiry by Royal Commission. Truth is truth to the end of the reckoning, and there is nothing to fear from free discussion, but much to fear from undue haste.

## PARAFFIN IN PLASTIC SURGERY. (a)

By STEPHEN PAGET, F.R.C.S.,  
Surgeon, West London Hospital, &c.

THE author stated he had injected paraffin in about seventy cases of depressed nose and ten of prolapse of the rectum or vagina. For the nose cases, he used a paraffin melting at 114° or 115°F., prepared by Rogers, 327 Oxford Street, London, and a syringe made by Dröll, of Frankfort, recommended by Dr. Stein, of Wiesbaden. In these nose cases it was of the utmost importance not to attempt too much, but to be content with the least improvement that would content the patient. Those cases were most favourable where the skin was loose, free, soft, and healthy, and the tip of the nose was well-formed and in the middle line. Those cases were less favourable where the skin was rigid or shrunk. And those were wholly unfavourable where the skin was scarred, adherent, pinned-down to the deeper structures, and wasted. Everything depended on the state of the skin; if that was favourable, it did not matter if the septum were perforated. He had not had any case of embolism or sloughing, and he believed that these dangers might always be avoided; the more common danger was that of attempting too much. The least excess of paraffin impaired the result of the injection, and the surgeon ought to attempt nothing more than just to make the patient unnoticeable. He advised that a general anæsthetic should be given; that gentle pressure should be continued for ten or fifteen minutes after the injection, till the paraffin was perfectly rigid, and that a cold wet compress should be laid over the upper part of the face for a day or two. No sort of nasal splint was of any use.

Of the cases of prolapse of the rectum or vagina, treated by injection of paraffin under the mucous membrane, two had relapsed, and in one the injection had been followed after some months by a

stricture of the rectum; but the majority of the cases had been successful, and the injection would avail even in cases where numerous operations had failed. In these cases of prolapse, the purpose of the injection was to strengthen and thicken and approximate the walls of the cavity, and thereby to hold up the slack redundant mucous membrane, and prevent its eversion. A paraffin melting at 104° or 105° was hard enough. It must be injected immediately under the mucous membrane, into the loose submucous tissue, and no deeper. In prolapse of the rectum, two or more nodules or hummocks of paraffin should be raised, in the lower two inches of the rectum, just under the mucous membrane; these being apposed would tend to prevent prolapse and leakage, but could not hinder the natural action of the bowels, and a good result might be obtained, even though the sphincters were destroyed or useless. In prolapse of the vagina a patient might be enabled to do without a pessary, or, at least, might be kept from prolapse by paraffin plus a pessary, though the pessary alone had been useless. But, of course, a cystocele or a very bad prolapse of the vagina was not easily cured, especially if the patient had to work hard for her living.

## Austrian Clinical Lectures.

### ON COLOUR HEARING.

By Professor HEINRICH CHALUPECKY, M.D.,  
Docent-Chair of Medicine, University of Prague.

[FROM OUR VIENNA CORRESPONDENT.]

IN reviewing our knowledge on this speculative phenomenon of the doubling of human sensations, the lecturer said that it would be instructive to examine more minutely the different theories advanced on the subject. The first of these views is given by Nuel under the title of "Central Irradiation," wherein he contends that the explanation of the double sense of sound and colour, or sound-producing colour, is due to the proximity of the hearing and seeing centres with a disposition to hypersensibility. This sensitive state permits of a stimulus acting on one to pass over to the neighbouring centre, and act on the second centre with a positive result in either colour or sound.

Steinbrugge's view of the phenomenon is that the nerves conveying sound and sight lie in close communion with one another, so that the stimulus, passing along the communication, is transmitted equally to each centre with the double result—i.e., one peripheral stimulus produces both hearing and seeing.

Thorp thinks the confusion of colour and hearing is intra-cerebral where fine fibres connect the acoustic with the optic nerve.

Now the objection to these three theories is that the principle does not apply to all cases. To the first it is objected to on the ground that the cortex is in connection with all the other centres; how, therefore, disposition can affect two centres is difficult to comprehend. This same objection applies to the second theory. Pedrono raises a similar objection to the third. These aberrant fibres referred to are common in the brain between organs of sense where no such anomaly exists.

Urbantschitsch has recently applied himself experimentally to discover the real connection, and finally concludes that the phenomenon is a reflex

(a) Abstract of Paper read at the Oxford meeting of the British Medical Association.

action. He found that by applying equal stimuli—*i.e.*, strong light and loud sounds—similar results could be produced. Again, if strong light were applied to the eyes for some time the auditory nerve became tired and dull, and *vice versa*. Another of the experiments conducted was with a grey surface slightly undulating, on which the patient looked, and near to this surface was a tuning-fork. On continuing the gaze after the tuning-fork was sounded the patient could see red and yellow lines on the grey surface, and finally all the rays of the spectrum appeared to him. This interesting experiment does not prove the double sensation, but when we find the retina exhausted by the effect of sound, we must conclude that the stimulus has a very close connection with the auditory apparatus. Here again we must distinguish between retinal exhaustion and retinal disturbance. By intense gazing at any object the blood-vessels of the retina can be so altered that chromatopsia is induced—*i.e.*, colours, rings, &c.—simply by the muscles of the eye checking the free circulation of the blood through the finer structure of the eye-ball.

It may be noted here that these are the more recent opinions on the subject, which are not a great deal in advance of the older ones. In 1848 Cornaz observed that an increased colour sensation was the anti-analogue of colour-blindness. At a later period Marcé adopted a scale of hyperchromatopsia which more recently has been developed by Albertoni in connection with a modulated scale of sounds which had been acknowledged as defective in the earlier experiment, as it is frequently observed that the patient who could not distinguish colours very well was as bad at recognising or distinguishing notes in a scale of sounds. This led to the establishment of a scientific scale of corresponding sounds that were defective in the colour-blind patient. It was found by observation that red-blind patients could not distinguish the G tone, while green-blind were unable to differentiate the D sound, which were fixed at Hauth's scale, and subsequently extended to G, E, C, and followed in the spectrum to C, D. Preyer deduced another on this same basis by light and vibrations. He found that the tone C produced a brown colour, and the tone D a red colour. In the same way he found E to be orange, F yellow, G green, A blue and B violet. With the assistance of the Italian School of Harmony, he endeavoured to elaborate this scale still further by combining colours, such as red-green and violet, and in harmony with D, G, B. At a later period, Castel combined these two systems, which now form one under his name. Notwithstanding all this scientific parade, we are still without the real cause of colour-blindness, unless we infer from these observations of sound and light that both organs of sense were defective. Beyond this deduction, no theory of the production can be formulated to account for the phenomena, and we are thus forced to look in some other direction for a better explanation.

The theory of evolution is found to be more satisfactory to the speculative mind. In the lower animals one nerve centre has all the functional activity of the differentiated brain of the higher animals. Thus it is argued, where a double sensation exists the brain is not fully developed, or has not reached the normal standard of evolution. It is well known in practice that these malformations are hereditary, and that double sensations of hearing and seeing are atavistic in character. This

argument would be perfectly easy and lucid if Hilbert would not disturb the calm repose with an awkward question: How is it that this acoustic-photoism often occurs in the short interval of waking and sleeping? Does the stimulus excite two senses—hearing and seeing—after consciousness is lost? He is inclined to interpret this phenomena in a different manner, and thinks the sensitive condition of sound-producing colour mostly belongs to the young, to disappear as years roll on; hence senile decay is what we have been prone to call the normal state of the brain, which, according to this reasoning, is only senile involution of the organism.

After reviewing such diverse opinions, one is driven to the conclusion that the double sensation is only an exalted condition of the entire cortex of the brain, or, in other words, due to cortical hyperæsthesia, and the best explanation after all our efforts may be found in the clinical experiment of Cololian and Rodiet, who produced cortical hyperæsthesia with alcohol, whose acute stage produces many hallucinations. With these patients it is no uncommon thing to produce in any two of the special senses the opposite effect. By percussing the surface of the body the alcoholic can often hear someone talking, or see different colours. Reasoning in this way, one is inclined to ask himself if this double sensation of light-producing sound is another form of hallucination, when all the senses can be taken in detail. It seems that hallucinations are the product of irritated nerve centres, which may be simply from irritating the centre itself, such as with the toxic alcohol, or the stimulus produce a similar result; hence we may have either central or peripheral stimuli producing the same result. Absinthe and haschisch are still more excitant or epileptic in their action than alcohol. The latter being an Arabian extract of cannabis indica, and a stimulant which Gautier tells us that he drank himself to produce colour tones, which he describes as red, green, blue, and yellow, which he could perceive in distinct waves with different sounds. In another part of his work he tells us that the playing of a piano made such a noise that certain of the notes felt to him as arrows piercing his heart, while the other tones were blue, red, &c. Baudelaire, the poet, had the misfortune of indulging in haschisch, and taste and smell are associated with colour and tones, which he makes free use of in his poetry.

There are other well-known toxins, such as san-tonin, which at first produce xanthopsia, followed by a violet colour-blindness, burning of the skin, and finally a dull insensible feeling—*i.e.*, first hyperæsthesia followed by anæsthesia.

With these facts before us we have only to imagine a cortical hyperæsthesia of a congenital nature, and we obtain all the factors necessary to produce sound-photopsia or aberration of the other senses. Our famous painters, poets, musicians and mechanics belong to this class of cerebral deviations. This sound-stimulus producing colour is well marked in the poet Binet, whose verse is crowded with "coloured spectra" which he tells us were produced by the strains of music. We may therefore conclude that all these elaborate theories of proximity of centres on nerve fibre connections with central ganglia, and nerve heredity, or atavism are speculations of a very abstruse nature and not at all borne out by pathology or physiology. Sound-hearing may be defined as a physiological deviation of the cortex which, if weakened, over-

worked or stimulated into a condition of hyperaesthesia, feeble stimuli are sufficient to produce abnormal physiological results.

## THE EVOLUTION OF THE SANATORIUM TREATMENT OF CONSUMPTION, (a)

By T. N. KELYNACK, M.D., M.R.C.P.,

Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.

GENTLEMEN,—The so-called "open-air" treatment of consumption has been subjected to what a vulgar public is accustomed to approve as the gentle art of "booming." At first discountenanced and ridiculed, it has rapidly grown in favour both with the profession and the public. But an injudicious optimism on the part of the laity, and an ill-judged and unqualified advocacy of some members of the medical profession, have not unnaturally tended to turn the tide of unlimited hopefulness, and with the ebb of an irrational enthusiasm there is a real danger that the true place of the sanatorium in the arrest and alleviation of pulmonary tuberculosis may not be properly apprehended and much of the principles and no little of the practice of regulated hygienic treatment of consumption be discountenanced and neglected.

It cannot be denied that much disappointment has resulted in many quarters in consequence of the failure of the open-air treatment to fulfil all the miracles of healing which unscientific enthusiasts claimed for it. The new treatment, as it is still sometimes designated, has been advertised and exploited as though it possessed specific therapeutic properties. And in the upspringing of institutions professing to provide rational hygienic treatment of consumption it must be admitted that establishments have come into being the conduct of which has not gone to encourage faith or develop practice in a systematic and scientific management of the disease.

Undoubtedly in the rational application of hygienic methods we have the most effective means known to medical art of combating pulmonary tuberculosis, and it will be lamentable if, through lack of judgment, insufficiency of knowledge, or selfishness, the pendulum of public and professional opinion be allowed to swing back from its position of illogical and unscientific hopefulness to a position of equally illogical and unscientific hopeless despair, when by a clear statement of the true position as evidenced by pathological research and clinical experience an attitude of mind can be reached which is willing to prove all things and hold fast to that which is clearly demonstrated to be good.

Having studied the development of the sanatorium movement in this country and visited most of these institutions in Great Britain and Ireland devoted to the management of consumptive cases, I venture, in the short time allotted to me, to endeavour to place before you the main features in the evolution of the modern sanatorium for the treatment of consumption, to indicate somewhat of the nature of the present practice followed, and to forecast something in regard to the future.

(a) A Lecture delivered at the Post-Graduates' College and Polytechnic, London, on Tuesday, July 5th, 1904.

### THE GROWTH OF HYGIENIC TREATMENT.

Every healthy man is slow to realise the advantages which accrue from a regulation of his life in accordance with hygienic principles. The need for public sanitation he readily admits, but the practice of personal hygiene he willingly neglects. It is easily understood, therefore, how difficult it has been to make the average mind realise that hygienic methods were all-important in the management of the morbid, and especially in such a disease as pulmonary tuberculosis.

There seems to be a general idea that our views and practice in regard to the hygienic treatment of consumption were made in Germany; but, whilst we willingly bear witness to the directing and inspiring influence of Brähler, Dettweiler, Walther, and others, it is but right that we should accord due honour to English and American pioneers.

[Quotations were here given from the writings of such pioneers as George Bodington, Henry MacCormac, Parrish, and Benjamin Ward Richardson.]

### THE SANATORIUM OF TO-DAY.

Interesting and instructive as it is to consider the development of what we may term the sanatorium idea, it is more important to investigate the principles which underlie the institutional treatment in the present and study the methods employed in the various establishments which now stud the country.

Sanatoria now exist for all sorts and conditions of sufferers. The wealthy may enjoy many of the luxuries of hotel or club life, while the pauper can at least be supplied with the inexpensive necessities of fresh air and exercise. And it is well that provision should be made for patients drawn from every rank of life, for consumption is no respecter of position. But it is most necessary, if the method is not to fall into disrepute, that the essential principles of the hygienic treatment be insisted on, and the method of their application directed by medical authority.

At present there exists the widest diversity. Some sanatoria are conducted in accordance with a slavish imitation of the so-called "Nordrach system," and procedures are insisted on ill-suited to the character and constitution of most British patients.

In certain institutions there is the greatest laxity, patients being left to order, in great measure, their own manner of life, and receiving but little better attention than residents in a convalescent home. Several so-called sanatoria exist where there is no resident medical officer, and in not a few the chief work devolves upon a recently qualified junior and necessarily more or less inexperienced resident. A number of lady medicals are taking up sanatorium management. A considerable number of those responsible for the medical conduct of sanatoria have themselves been the subjects of phthisis, and not a few have come under the influence of the masterful personality of Walther at Nordrach. With some of these there would sometimes seem to be a tendency to elaborateness of details and all-pervasive supervision which is liable to rob the patient of all originality and initiative, and undoubtedly sometimes go far to develop neurotic characteristics. Wide differences also exist in regard to nursing in sanatoria. Those who follow the Continental methods of procedure discountenance the presence of the trained nurse, and some even disallow

attendants to wear anything resembling a nurse's garb. It is undoubtedly well that patients should be prevented from falling into habits of selfishness and encouraged to do for themselves such matters as will not interfere with their restoration to health, and those patients belonging to the working classes should be expected to assist in actual work as far as their condition will allow. But we believe that a well-trained nurse is most desirable, not only for the carrying out of rational therapeutic measures, but also for the maintenance of what we may term the educational atmosphere of sanatorium life.

Much discussion has taken place regarding the structural form and situation of sanatoria. These establishments present remarkable contrasts. Some are almost palatial in their design, lavish in their equipment, extravagant in their upkeep, and such as can only be brought within the means of the wealthy. Others are simple in construction, bare and comfortless in their fittings, inexpensive in their conduct, and intended for the comparatively poor. Many are admirably placed in sunny and protected regions, while not a few are situated on exposed, damp, windswept sites. But the remarkable fact comes out clearly that while some cases do well under the simplest, and it may be seemingly most unfavourable, conditions, others, even when placed in what theoretically should be the most advantageous life, do ill.

#### PRINCIPLES OF SANATORIUM TREATMENT.

But however widely sanatoria may differ in the details of procedure, it is most desirable that the general principles guiding action should be similar.

In selecting a suitable case for sanatorium treatment it is well to remember that hygienic management seeks to secure :

I. The removal of the patient from fresh invasion by the tubercle bacillus, and separation, as far as possible, from all influences aiding its introduction.

II. The establishment in the patient of processes of repair and the development of the highest powers of resistance.

To this end the instruments employed are :

1. Continuous exposure to fresh air.
2. Free access to sunlight.
3. Regulated rest.
4. Controlled exercise.
5. Abundant feeding.
6. Obedience to hygienic requirements.
7. Strict medical supervision.

I cannot stay now to explain the manner of action of these various factors, but they should be employed with a clear apprehension of their physiological influence and therapeutic value. Unfortunately, at the present time too much in sanatorium treatment is lacking in scientific precision and savours too much of mere empiricism.

And such a state of affairs is likely to persist so long as discordant views prevail regarding the pathology of pulmonary tuberculosis and widely divergent views are promulgated regarding its origin, spread, arrest, and prevention.

It is much to be regretted that so little is being done in the sanatoria of this country to encourage systematic scientific research.

It is well that we should remember that much connected with the so-called hygienic management of consumption is at present in little more than the experimental stage.

#### SELECTION OF CASES FOR SANATORIUM TREATMENT.

There is need for the greatest care and the most judicious discrimination in selecting cases for sanatorium treatment.

Too often resort to open-air treatment is advised as though it possessed the virtue of a definite specific. In many instances patients are sent by their medical advisers to sanatoria as a last resort. By a reckless advocacy of institutional treatment much harm is being done to many an individual, and public sympathy and support are in danger of being discouraged and even alienated.

All cases of consumption should no doubt be treated in accordance with strict hygienic principles, and generally speaking the best hygienic management can only be provided in properly constructed and well-conducted sanatoria. But at the present time with the limited accommodation available for the indigent and those of limited means it is most desirable that there should be a wise selection of cases. This is abundantly clear when we remember that in England and Wales alone considerably more than 40,000 deaths are registered every year from phthisis, and that between the ages of fifteen and twenty-five one-fourth of the total deaths are due to this disease.

But prognosis in pulmonary tuberculosis is beset with difficulties. Many of the old precepts have ceased to have directing value. The pessimism of past days has given place amongst not a few to an optimism which unfortunately is oftentimes groundless. It is sometimes claimed that phthisis is the most curable of chronic infective diseases, and while pathological evidence and clinical experience go far to afford basis for such an opinion, yet I am convinced that we should always do best to regard phthisis in all its forms as a most grave malady. Many cases certainly do arrive at a complete arrest of the pathological process, but among the poor and working classes quiescence is often only temporary, and relapse, re-infection or a re-awakening of the slumbering ill only too commonly occurs.

Hygienic treatment may accomplish much. It undoubtedly affords the most scientific and the most successful means for a rational combat with consumption. But the powers of the open-air treatment are limited, and it is detrimental both for the individual and the charitable public to make claims which experience cannot support.

We must view the prognosis of phthisis in the light of present-day knowledge and submit every case to individual study before advising resort to what may be an expensive and ultimately useless institutional control.

[The various points guiding prognosis in cases of phthisis were then discussed and indications given for judicious selection of cases for sanatorium treatment.]

#### THE FUTURE OF THE HYGIENIC TREATMENT OF CONSUMPTION

As I have already indicated, the so-called hygienic treatment of consumption undoubtedly affords the most trustworthy and successful means for dealing with tuberculous cases. It is, of course, possible that medical science may discover some method whereby a special serum or other body may provide prophylactic powers or act as a definite antitoxin, and so necessitate a modification in our institutional treatment.

Meanwhile much may be done to extend and amplify the application of such hygienic measures as clinical experience has shown are rich not only in preventive force but also effectual, to a great extent, as curative and alleviative agents.

From what I have said regarding the necessity for a careful selection of cases, it is clear that much remains to be accomplished in the way of a more precise differentiation in the grouping of patients.

It is most undesirable that so-called incipient cases should be allowed, as is now so often the case, to associate with persons in an advanced stage.

Institutions located in or near our large centres of population should be used mainly for advanced cases and for the purpose of observation of those in which prognosis is doubtful.

Cases in which arrest is at all possible should at once be given the opportunities of a country sanatorium, which, particularly in the case of the poor, should not be difficult of access from centres of work.

There is great need at the present time for suitable homes for those helpless and hopeless cases occurring among the poor and labouring classes, for whom there is now practically no refuge save the much-dreaded workhouse.

Undoubtedly the action of most general hospitals, special hospitals for consumption and sanatoria, in refusing admission to all manifestly hopeless cases necessitates the retention of large numbers of dying phthisical patients in homes devoid of all hygienic requirements and such as facilitate infection of relatives and friends, many of whom are often peculiarly predisposed to contract the disease.

Efficient sanatorium treatment, it must be remembered, can never be inexpensive. Means must, however, be found for dealing with the immense number of those who, self-supporting whilst in health, when smitten by disease are compelled to join the ranks of the dependent. At the present time there is abundant sanatorium accommodation for the well-to-do. Much is also being done to meet the requirements of the poor, but for sufferers belonging to the struggling professional and business classes adequate opportunities for hygienic treatment are few and far between.

Much will also have to be done in providing for satisfactory "after care." Only too frequently a patient who has done well during residence in a sanatorium speedily relapses because, in the absence of systematised means to secure suitable work and a hygienic dwelling, he or she is compelled to return to the old occupation and the former insanitary mode of life; and thus time, skill, and money are expended in vain and a desirable form of treatment is brought into disrepute.

I am afraid that in this country there is at the present time but little chance of national friendly societies and labour organisations rendering much assistance in the establishment and maintenance of sanatoria for the working classes, after the manner adopted in Germany. Much may be said in favour of the suggestion to hand over London consumptives to the care of the Metropolitan Asylums Board.

I am also of opinion that some of the many convalescent homes which abound in this country might well be devoted to the further up-building of

those who have passed through our public sanatoria, where, it must be remembered, the patient can usually only be retained for a comparatively short period, long enough, it is true, to teach the necessity for and the best means of maintaining the hygienic life, but oftentimes quite inadequate to procure anything approaching a complete arrest of the tuberculous process.

I do not propose to discuss the advantages and disadvantages of compulsory notification in relation to any public system of sanatoria. A voluntary notification is in force in many important centres, and it is clear that reliable information regarding the presence of tuberculous subjects and the conditions under which they have fallen ill and the arrangements for their relief and treatment would be of the greatest service if wisely used not only for the safety of the State but the benefit of the individual sufferers. It is very necessary, however, to bear in mind constantly that among many persons in all ranks of life there exists an unreasonable, and I think I may safely add an unwarranted, fear of any association with the phthisical, and as is well known already in America this phthisiophobia has much increased the difficulties in founding and maintaining sanatoria and otherwise adequately dealing with the consumptive.

Gentlemen, it is well, if we would retain the confidence of the public and maintain the dignity of our profession, that we should readily admit that we are still far from a clear understanding of the nature of the disease we term pulmonary tuberculosis.

Treatment still lingers for reliable direction from pathology.

We have in great measure shaken free from the trammels of many erroneous views, but we are still to a large extent groping in doubt and uncertainty.

Sanatorium treatment has accomplished much, and I believe is destined to have far reaching influence, not only in bringing benefit to the individual sufferer, but in making clear to the public the advantages of the hygienic life.

But we must be willing to admit that much connected with the so-called hygienic treatment of consumption is still in the experimental stage.

Let us therefore continue to maintain the truly scientific attitude; and while extending a critical sympathy let us, with the true insight of the rational therapist and the far-seeing wisdom of the sanitarian, remember that the modern sanatorium for the consumptive is still in process of being.

### Clinical Records.

#### HEMIANÆSTHESIA AND CONSCIOUS TROUBLES OF SENSIBILITY IN SLIGHT AND OLD HEMIPLEGIA.

By G. A. SCHERB,

Assistant-Professor to the Medical School; Consulting Physician to the Mustapha Hospital, Algiers.

PROFESSOR O. MARIE, my distinguished master, once asked whether, in the case of a hemiplegic, a well-marked organic hemianæsthesia could last for years.

In 1898, MM. Degerine and Long reported to the Society of Biology of Paris that, as the result of numerous microscopic researches in seriated sections, clear cases of sensory troubles, persisting

until death, occur among hemiplegics. (a) The condition may exist many years after the initial "stroke," even though the motor troubles have considerably diminished. They have pointed out that a slight lesion accompanied with trifling motor troubles involving the external part of the thalamus was likely to bring about an obstinate hemianæsthesia by destroying that grey substance which constitutes a relay or a stage between the ascending peduncular ways and the thalamo-cortical fibres. One understands, under these circumstances, the possible existence of a more intense and lasting hemianæsthesia than the concomitant hemiplegia, by reason of the sensitive ducts being here still, as in the *calotte's* region, more or less distinct from the motor paths.

MM. De erine and Egger (1903) have, besides, recently reported a case absolutely confirmatory of those views, which were rather novel and opposed to the classic teaching of Charcot, who always said that the lower part of the internal capsule contains, still isolated, the sensitive bundle. This is what induces me to state the particulars of the following case, carefully recorded by M. De Mouzon, an outdoor student attached to my wards of the Mustapha Hospital:—

D., æt. 49, farm labourer, native of La Lozère, a short but thick-set and vigorous highlander, had a fall, eight years ago, from a height of about two metres into a vat. Owing to his having been unconscious, he could not give any information as to the cause of his fall, nor could he say what part of his body was hurt. This point is of importance, both from the diagnostic and the forensic point of view. Now, suppose that man believed himself hurt and crippled in the course of his work, there would be great reservations to be made, for one should put oneself the question whether there had not been a previous ictus which had determined the fall. He did not know why or how he fell, and, as he came to about half an hour afterwards—that is, when his mates took him out of the vat—he had no sore on the head nor any indication whatever of a trauma of the skull. However, he kept his bed for twenty days, for he could not move the right side of his body. His speech was not at all affected, and his face only bore slight traces of motor troubles, which have persisted up to now. At the end of those twenty days he could make a few steps, and he walks to-day almost normally, and he must be attentively observed to perceive that in walking he drags his right leg slightly. Thus he shows Babinski's sign on the right side by pricking the right sole, with exaltation of the patellar reflex and of the wrist. If he tries to whistle, there is a deviation of the left side of his mouth, and he whistles badly; if he puffs up his cheeks by obliterating his lips, the right labial commissura appears incompetent directly. No muscular atrophy exists, and Mr. Bordet, a friend of mine, who has submitted him to an electro-diagnosis of the shoulder muscles, where the motor deficiency is most marked, has found normal electric reactions. However, the patient does not cease to complain that his motions on the right are impeded. No noticeable weakening of the muscular strength was evident on the right side, but that strength is somewhat transient; it exhausts itself quickly; he is unequal to any continuous effort. Moreover, he cannot raise his right arm above his head

—on account of the peri-arthritis, no doubt—and he suffers from his right shoulder if he ventures to raise his right arm above the horizontal line. Obviously hypertrophied is the right hand, and that uniformly. That constitutes the trophic troubles which are the first indications of that hypertrophied hand that one sometimes meets with in the case of hemiplegia. No deviation at all of the vertebral column. The pupils are even and the eyesight is not impaired, no shortening of the visual field has taken place, while olfaction, hearing and taste have remained normal. And there is not any hysterical stigma.

From the first day my attention has been drawn by the sensitive deficiency. I have had this case under observation for a year and it has not varied. Besides, the patient himself is aware of it all; the first remark he made when he began using his right hand was that he did not feel the heat of the bowl of his pipe. The sensitive troubles have in the study thereof been serial; upon the whole—and that is also the rule in organic anæsthesia proceeding from a cerebral lesion—they are prominent chiefly at the extremities of the limbs.

*Brush Examination.*—Right sided hemianæsthesia. In the upper limb, the troubles predominate at the hand and by degrees diminish at the elbow and arm, only to increase again at the level of the shoulder. The foot is almost entirely anæsthetic, the leg and the thigh are rather less. The trunk and the face are hyperæsthetic on the right, and the mucous sensibility of the mouth on the same side is impaired.

*Pressure Sensation.*—Considerable difference exists between the faculty of the left side and that of the right.

*Sensibility to Pricking.*—Same observations as in examination of tactile feelings.

*Thermæsthesia.*—Considerable reduction in the extremities, with delay or slowness in perception. With regard to cold, however, there is no lack of sensitiveness in this direction. Experiments have been made with ice and a hammer heated in boiling water. It is to be noted that the right shoulder region shows a dull sensibility to temperatures which the hand fails to perceive.

*Perception of Passive Segmentary Attitudes.*—The attitudes imparted to various segments of the right upper limb are not altogether lost. Now, as for flexion, supination, abduction, pronation, &c. Let the right arm of the patient be placed in a certain position; he cannot place his left arm in a similar position if he shuts his eyes. In trying to do so, slowness and groping uncertainty prevail.

In the lower limbs motions are well performed.

*Stereognostic Sense.*—Almost absolute disappearance in the right hand. Moreover, if, without the control of his eyesight you give an ordinary glass to the patient to weigh, he directly values the weight thereof at 2 kilogrammes. Most gross mistakes of weight of this kind are made about very common things. He does not know them by feeling them, and he is incapable of valuing their weight.

*Conclusions.*—It is evident that there are to be found all the attributes of organic hemianæsthesia through lesion of the encephalon. These troubles are fixed and conscious, dating from about eight years back, without any change; they are not, however, accompanied by hemianopsia, and motor disturbances are very slight indeed. Still, it is on the right shoulder that they predominate on account of some ankylosing arthritis; the most

(a) "Traité de Médecine" de Brouardel et Gilbert. T. viii.

profound troubles of sensibility lie in the perimeter of the scapular region, on account, undoubtedly, of the fact that it is there the sensory re-education could less easily be made, owing to the fact of restricted motions. Nevertheless, it must be insisted upon that the shoulder troubles do not in the least affect any metameric disposition.

Thus it is exceedingly probable that in the case of D. the matter is one of a very slight lesion of the thalamus in its external and posterior part, as the motor deficiency is, indeed, so little developed. That lesion, if extended backward, would have resulted in hemianopsia; if, on the contrary, forward laterally, these motor troubles would have been more serious.

A solely lenticular or capsular limited lesion would not have been accompanied by sensory troubles so deep and persistent. This case is one to study carefully from a clinical point of view. It comes absolutely within the range of these sensory definitive posthemiplegic troubles of which MM. Dejerine and Long try to fix the anatomical substratum.

### The Out-Patient Departments.

*Dermatological Cases under the care of Dr. P. S. ABRAHAM.*  
[REPORTED BY DR. G. N. MEACHEN.]

CASE I.—*Extra-Genital Chancre from a Bite.*—A single man, æt. 29, a stall-holder, came with an obstinate sore upon the back of his right hand. The history was that he was engaged in a fracas with his brother on the night of May 30th. This latter individual was in a state of intoxication, and was known to be suffering from syphilis. In the course of a struggle, the patient was bitten by his antagonist upon the back of the right hand. He did not take much notice of the occurrence at the time, but the spot remained somewhat inflamed for some time afterwards. At the expiration of a month he observed a distinct sore place over his knuckle and some painful lumps appeared under his arm. When seen, on August 26th, 1904, there was an oval, ulcerated sore,  $1\frac{1}{2}$  inch in its longest diameter, situated upon the dorsum of the right metacarpophalangeal joint. The edges were raised and infiltrated, and the surface was raw and discharging ichorous matter. About one inch behind it was another sore, one-quarter the size, and of a punched-out appearance. The axillary glands were enlarged. A typical secondary eruption of the scaly, maculo-papular type was present upon the body and limbs, which the patient stated had appeared soon after the sore. Seven weeks ago the throat was troublesome, and the original sore began to spread and to ulcerate. On examination, the fauces did not present any abnormal appearance. He had not had any medical treatment.

The history of accidental inoculation in this case was perfectly clear, but even if this had not been so, the raised and infiltrated character of the lesions upon the hand with their serous exudation would have been quite sufficient to form a diagnosis, without asking any further questions or examining any other part of the body. The multiplicity of primary chancres was not so uncommon as was generally supposed, particularly when the lesions were extra-genital.

The patient was at once put upon vigorous anti-syphilitic treatment.

CASE II.—*Extensive Tinea Circinata.*—A married man, æt. 41, presented himself for treatment with an eruption extending almost completely round his neck, which he had noticed for the last three months. He believed he contracted it at a barber's shop. On examination, a collar-like rash could be seen of a dark red colour and with a raised margin forming a ring practically all round the neck. The borders were slightly scaly, and here and there the more central parts appeared to be clearing up. The nuchal and occipital regions were the most affected, but the disease

had not encroached upon the scalp. Patches of a similar nature were also seen in the left ante-cubital space and upon the extensor surface of the right elbow. There was no inflammatory reaction nor pustulation of the surface. A scraping from the border of the patches upon the neck examined in liquor potassæ revealed an abundance of mycelium.

The comparative rarity of *tinea circinata* spreading in a collar fashion round the neck was commented upon. Extensive areas of ringworm of the body were, however, frequently seen in the groins and thighs, sometimes mounting upwards upon the abdomen. The so-called "*eczema marginatum*," applied to these eruptions was not a bad clinical term, though they had nothing whatever to do with true eczema. They were frequently mistaken for seborrhœic dermatitis. It was important in all cases to take a surface-scraping, for in this way only was a correct diagnosis possible.

This man was given an ointment containing half a drachm each of carbolic and salicylic acids to the ounce of vaseline.

## British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

### XIII.—CHAGFORD.

DARTMOOR has long fascinated the favoured few and closely held the allegiance of artist and antiquary, sportsman and naturalist. (a)

Its topographical features and climatic conditions well fit it as a desirable upland health station. With the coming of rational ideas regarding the prophylactic and curative value of the hygienic treatment of the human subject, the advantages of this tableland region of Devon should become well known. (b)

The rampart is high and the average temperature low. Penetrating mists are very prevalent, but appear to exercise a soothing influence on many cases subject to certain laryngeal and respiratory affections. Severe frosts are experienced in winter, and the bracing character of the air is highly beneficial for many cases able to undergo active exercise in the open. Much cloud prevails at all times of the year, and lessens radiation from the ground.

Among the many centres bordering on Dartmoor which might well be developed into sanatoria, Chagford merits a foremost place. It lies at an altitude of 650 feet above sea level, well sheltered amid the hills on the north-eastern slopes of Dartmoor. The scenery is varied, and highland, lowland and woodland are all close at hand. The pedestrian has almost numberless walks of peculiar attractiveness, the invalid can quietly enjoy the benefits of salubrious air and bracing breezes, the feeble, contemplative, or invalid can find peaceful sport on the banks of the Teign, while the antiquarian and naturalist will find ample material for fascinating study. In short, the district is rich in natural health-giving features, and mind-stimulating characteristics, so that both physical and psychological influences can be combined in the treatment of disease.

We have resided at Chagford during summer days and thoroughly investigated the neighbourhood, and consider it an almost ideal country station for the overworked and brain-fagged. It should prove a perfect holiday resort for those who find in inland uplands restorative properties. For certain phthisical cases it offers admirable opportunities for open-air treatment. An excellent private sanatorium above the village of Chagford is already doing much good work, as we have been able to ascertain from personal inspection.

The district is not well suited to heart cases, and some patients will find the air too bracing, and during winter months the exposure too severe.

(a) See such a classic work as "*A Perambulation of the Antient and Royal Forest of Dartmoor.*" By the late Samuel Rowe, M.A. Third Edition, 1902. Consult also "*A Hundred Years on Dartmoor.*" By William Crossing. Fifth Edition, 1902.

(b) See "*Dartmoor and its Surroundings.*" By Beatrix F. Crosswell. Third Edition, 1903. London: The Homeland Association.

During spring and summer adolescents and delicate children should be greatly benefited by residence in this district.

There are several good hotels and comfortable lodging houses at Chagford, and excellent apartments may be obtained. (a)

Chagford is about 193 miles distant from Waterloo, and may be reached by a drive of about an hour and a half from Okehampton (L. and S.W.R.).

It can also be approached from Yeoford junction.

Perhaps the most convenient access is by Exeter, Newton Abbot, thence by rail to Moreton Hampstead (G.W.Ry.), and coach to Chagford.

Recently services of motor cars have been opened from Exeter (L.S.W.Ry.) and Moreton Hampstead (G.W.Ry.) to Chagford.

## Special Articles.

### THE CHEMISTRY OF FINE WINES.

BREWING has become a fine art in which the latest scientific discoveries are brought to bear, either to cheapen the cost of production or to ensure more perfect preservation. This applies with equal force to the "brewing" of wine, for we hardly know what other term to apply in respect of a beverage which undergoes so many and such complicated manipulations before being delivered to the public. We know that the Bordeaux wine merchants receive huge quantities of crude undrinkable wines from the South of France, Italy, Algeria, possibly even from California and Australia, and that from these unpromising juices they somehow prepare a wine which is characteristically "claret." The great difficulty with which they have to contend is that of controlling the fermentative process, in other words, of "fixing" the finished product. They overcome this difficulty by adding gypsum, which, in contact with the tartar (tartrate of potassium), becomes transformed into sulphate of potash, the lime being thrown down as a tartrate. The presence of an excessive proportion of the potash salt is injurious to health, and a limit has been fixed by law, in France, though in practice it is by no means uniformly enforced. White wines undergo another treatment, like alum in bread, for the purpose of making them appear whiter than they are. The agent employed is sulphurous acid, obtained by burning sulphur in the barrel before introducing the wine. Any excess of acid gives a certain pungency to the wine which, if not necessarily harmful to the flavour is reputed to be injurious to health. Some time since the Paris Council of Hygiene formulated a recommendation to the effect that wines containing more than twenty centigrammes of sulphurous acid, or two grammes of sulphate of potash, per litre must be regarded as unfit for consumption. Acting on this opinion the United States Government proposes to prohibit the importation of all wines falling within the scope of this resolution, and it so happens that certain high class wines of Barsac and Sauterne proved on analysis to contain nearly thirty-eight centigrammes of acid and close upon three grammes of the potash salt per litre. The news naturally excited considerable emotion in the French wine trade, and influence is being brought to bear on the home authorities to declare inapplicable the standard laid down by the Paris Council of Hygiene, and to make the necessary diplomatic protests to foreign governments.

The case for the wine manufacturers does not strike one as strong. In the first instance they advance the highly technical and elusive argument that the authority of the Paris Council does not extend to places outside the city walls, consequently, that its dictum carries no weight in Bordeaux. This argument is hardly *ad rem*, because, if the standard be a reasonable one, it must occur to everyone that if it is not generally applied it ought to be, and, moreover,

(a) See Ward and Baddeley's "South Devon"; also Dartington's "Exeter, Torquay, and Dartmoor."

on the face of it, the resolution errs if anything on the side of indulgence. Another argument, more plausible than the one just mentioned, is that it is absurd to apply to fine wines regulations which were intended to regulate only the sale of the ordinary qualities of wine in general use. They point out that while an excess of chemical substances in the latter may be prejudicial to health, in consequence of the much larger quantity consumed, it has practically no importance in the high-priced wines which, they assume, are always taken in strict moderation. There is obviously a certain amount of truth in the argument, though too much stress must not be laid on the assumption of moderation, and the stomachs of the well-to-do merit fully as much consideration as those of the poorer classes.

In view of the immense political influence at the disposal of the wine trade in France the question appears to be one which ought to be decided by the sanitary authorities of the wine-importing countries and not by the producers. So far as we are aware, there is no legislation bearing on this point, though in practice the presence of foreign substances injurious to health in wines would, no doubt, bring them within the scope of the laws prohibiting adulteration.

We do not pretend to settle the question of what is the proper limit in this respect, but we would suggest that if an excess be prohibited in Paris and in the United States, the propriety of enacting similar restrictions is likewise worthy of consideration at home. *Avis à qui de droit.*

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 1st, 1904.

### STOVAINE—A NEW LOCAL ANÆSTHETIC.

STOVAINE is a new local anæsthetic derived from tertiary amylic alcohol, discovered by Fournau. It crystallises in little brilliant flakes, much resembling cocaine; it is extremely soluble in water. The physiological properties of stovaine have been studied by Billon and Lannoy, while Dr. Ponchet read an important paper on it at the meeting of the Academie de Médecine, from which it appears that stovaine is much less toxic than cocaine; it is a vaso-dilator, it possesses an antithermic action, and has evident antiseptic properties. Its therapeutic applications have been studied by Prof. Reclus, Lapersonne, Chaput, Huchard, and by Mr. Sauvet, dentist.

According to Mr. Chaput, the analgesic action of stovaine is identical to that of cocaine. It is less toxic than cocaine, and has a vaso-dilator action which, producing congestion of the bulb, suppresses syncope and allows patients to be operated on seated, and to rise immediately after the operation. Injected into the lumbar region, it permits all kinds of laparotomies to be made with ease.

Prof. Reclus said that he injected more stovaine than he dared do cocaine, and he was able to perform operations under its influence which he could not have done with cocaine. It was thus that he was able on the same patient, and at one sitting, to remove four voluminous varicose veins, two from each leg, without the slightest pain to the patient.

The domain of stovaine, like that of cocaine, appears to him to be circumscribed tumours, cutaneous or subcutaneous lupus, lipoma, fibroma, cancroïdes, extirpation of the phalanges of the toes or fingers, ingrowing nails, whitlow, (artificial anus, umbilical hernia, hydrocele, varicocele, castrations, laparotomy for non-adherent ovarian cyst, empyema (with resection of the ribs). In his hospital practice, two-thirds of the operations were done with stovaine.

Mr. Lapersonne considered that stovaine was called

to render excellent services in ocular surgery. By instilling stovaine into the eye, all operations on the cornea and even that for cataract could be done. Injected into the conjunctiva, it was superior to cocaine; the insensibility was complete in less than a minute, and gave sufficient time for the operation.

Dr. Sauvet, dentist, said he had employed stovaine instead of cocaine for the last two months, and obtained excellent results. He employed a solution of 0.75 per cent. for the extraction of teeth, and never had an accident.

Prof. Huchard insisted on the total absence of the slightest toxic symptoms. He injected one-fifth, one-fourth and a half a grain for costal neuralgia, and none of the patients complained of headache, nausea or vertigo. At first he recommended the patients to keep lying half an hour, but afterwards he allowed them to rise immediately after the injection.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 2nd, 1904.

At the Society for innere Medizin, Hr. Meyer spoke on

#### STREPTOCOCCUS CURATIVE SERUM

from clinical and experimental observations. The serums hitherto made use of had not been so successful as the diphtheria serums, as systematic clinical observations had been wanting. So much so had this been the case that prominent experts had declined to make use of them.

Two years ago he had commenced the attempt to immunise the larger animals, being guided in his experiments by two principles—(1) that the passage through animals had altered the streptococci, and (2) that the unity of streptococci had not been proved. He had, therefore, in his animal experiments used streptococci taken direct from the human subject only, and his preliminary treatment had been carried out by two forms alone, *viz.*, that found in suppuration and that met with in sepsis. In distinguishing the strains he had followed v. Behring's lead. These strains killed mice in doses of from 0.001 to 0.003 within twenty-four hours. He was of opinion that only a serum that is derived from strains that are pathogenic both for men and animals can be curative for the human subjects, and, therefore, can be made therapeutic use of. Animal passage, however, takes pathogenic property for the human subject along with it.

He had treated the following diseases in the human subject with his serum:—Simple angina, scarlatinal angina, erysipelas, articular rheumatism and sepsis. For a favourable result to be obtained only application of the serum was essential. According to his view, the serum destroyed the streptococci, and by this their toxins become free, so that with late use of the serum when the streptococci are present in large numbers, instead of a curative effect actual damage to the organism may follow.

Generally speaking, after one or two injections, a rapid fall of temperature and pulse takes place. This is frequently critical, sometimes not. Even in severe sepsis, a favourable turn often seems to take place. He would not recommend the use of the serum in mild cases, as such do all right with the usual means. But in cases that were evidently serious from an early stage he would recommend a trial with his serum, which at present was only prepared for experimental purposes in hospitals.

At a subsequent meeting, Hr. v. Openchowski gave a communication on

#### THE ACTION OF DIGITALIS IN REGARD TO SCLEROSIS OF THE RIGHT CORONARY ARTERIES.

Years ago he showed that digitalis acted on the left side of the heart only, and that the right heart was cut off from this action by narrowing of the right coronary arteries. This difference in action was of value as regarded the mechanism of the circulation. Many clinicians and pharmacologists had adopted his views. This dissociation was also of clinical importance. If the right heart acted more powerfully than the left, and set up dyspnoea, spitting of blood, oedema of the lungs, dilatation of the left ventricle, diminution in size of the right, a frequent small pulse (130), enlargement of the liver, and diminution in the quantity of urine, it was possible that more digitalis went to the right heart than to the left. This was rendered possible by dilatation of the right coronary arteries, through sclerosis and loss of power of contraction. The speaker had diagnosed three cases of sclerosis of the right coronary arteries, in which the left were only slightly attacked. In the last case the right coronary artery was doubled in size and completely sclerosed, whilst the left was narrow and elastic.

He then showed some cardiograms in which the right heart and jugular vein indicated heavy work, whilst the left curve was only slightly raised.

Herr Block showed a case of

#### BRACHYCARDIA.

A woman, æt. 48, of healthy parentage, and who on the whole had been healthy. Eighteen years ago she had ulcers on the vagina that were treated locally. Ten years ago the radical operation for cancer of the portio was performed, and at that time nothing abnormal was found about the heart. Four years ago, the patient was brought to the speaker for an opinion concerning violent attacks of pain in the stomach with diarrhoea. Examination showed symptoms of commencing tabes, but still there was no cardiac mischief. He had seen this patient off and on since that date. For three months she had suffered from peculiar attacks, which had become more frequent lately, up to ten or twelve in the day. The patient becomes suddenly giddy and unconscious and pale, the head is stretched backwards with, at the same time, a remarkable slowing of the pulse down to 36, 32, and 28. These attacks pass off in a short time. There is widening of the heart towards both sides, the beat at the apex heaving, the first sound dull, with a minimum capillary pulse. The symptoms of tabes had distinctly progressed. The cause of the brachycardia, considering the gastric crisis, was supposed to be an affection of the vagus, or it might be intra-cardiac. He had made an injection, but without result. The cause was therefore in the cardiac muscle, and all symptoms were dependent on a common cause, *viz.*, syphilis.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 2nd, 1904.

#### METEORISM AND LIVER CHANGES.

At the Naturforscher meeting Oppenheimer brought before the members the importance of liver changes in the diagnosis of disease, particularly peritonitis. From his experience in laparotomy sections, and also with animals, he is persuaded that liver dulness is an important factor in bonum, or in malum sensum, when temperature and pulse are not in harmony. The history of the case goes far to explain many morbid conditions when making differential diagnosis, but there often arise cases with

sudden deaths which we have difficulty in explaining. The same causes may be in operation that often occur in phthisical patients where enteroptosis or a falling of any of the internal organs, such as the liver, &c., may cause undue pressure and serious consequences. He related experiments on animals with the object in view of illustrating this accident by inflating the bowel and applying pressure to the chest, which rapidly produced cardiac stasis and sudden death.

Oppenheimer thinks that many of the accidents arising after the operation of anus preternaturalis are due to the high pressure in the bowel, which is not relieved after the operation.

#### INVAGINATION OF THE BOWEL.

Braun recorded sixteen cases of invagination of the bowel on which he had operated, eight of these being acute and seven chronic. In his opening remarks he said he could offer no explanation for the great number of these cases that occurred in other countries, especially in England, where acute invagination seems to be much more frequent than on the Continent.

The general opinion entertained by clinicians at the present time of the cause leading to this accident is spasm of a limited portion of the bowel and not, as was formerly believed, a paralysis of the bowel. Probably the diagnosis of this disease was not so accurately made as in other countries, which may account for the greater frequency to be found there. The symptoms generally met with in acute cases in children are sudden illness in a healthy child with tenesmus, vomiting, hæmorrhage, slimy mucus in the stools, with collapse and a distinct tumour at the site of the invagination to be found over the abdomen.

The chronic form is more difficult of diagnosis, which was demonstrated from preparations.

The treatment to be relied upon is operation as soon as the dislocation is observed. Removing it by manipulation or mechanical means, as reported in some hospitals, is not to be relied upon. Partial relief is no doubt frequent, but sooner or later the operation must be undertaken. Injecting air, water, and other fluids into the bowel have often been practised and may give temporary relief, but the bowel soon returns to its former malposition. It therefore remains to relieve by operation if possible what has not as yet been successfully done by resection. He considers the cause of this failure is due to the position of the buttocks after operation. Whatever may be the cause, he is in favour of an anus preternaturalis, which should be performed as early as possible in acute cases. It is often easy in these early opportunities to disinvaginate the bowel and relieve the sufferer without further delay or trouble. In the chronic form of invagination entero-anastomosis is considered the most successful operation.

It may be mentioned here that Eiselsberg has reported several successful cases by resection, but we conclude that they must have been in the very early stage.

In the discussion that followed, Kradel accentuated the difference of the frequency of this disease in England and Germany, for example. He had personally operated on eight cases of invagination without a single success. In three cases on which he did not operate, partial relief was obtained and the patient recovered. All of them were under one year, except one, and the youngest was eleven weeks old at the time of invagination. At the post-mortem the disinvagination was complete except in one case, which died of perforation and peritonitis. Whether operation is undertaken or not, the time necessary is exhausted. In

the case of reposition by injections of air or water, enormous pressure must be applied which cannot be long endured. If the operation be undertaken and disinvagination performed, it is difficult to prevent a return. Statistics seem to forbid heroic treatment. If the case be diagnosed early and operated on within a few hours there is hope for success; but if the intussusception has existed for any time the case is hopeless. Bartelsmann recommended injections and recorded four cases in which he was perfectly successful. The operation was not continued beyond an hour. Naunyn considered the diagnosis a very severe task in adults, but thought surgical operation the best. Braun concurred in this opinion of the diagnosis, which could easily be mistaken for any turning of the bowel or other enlargement.

Jächk related the history of two cases of disinvagination, which he accomplished with perfect success by injections. The ages were four and five months respectively, and the operations were undertaken nineteen and eleven and a half hours after the diagnosis was confirmed.

Pauli recorded the history of five cases which he had treated successfully.

Berge related a case which he operated on, and as soon as he had relieved the strangulated bowel the child died.

Wilmas discussed the production of invagination and described a few experiments he conducted on animals to prove that the cause was due to irritation of the longitudinal fibres of the canal, which causes it to fold in parts.

Kuhn reported 96 cases which he had observed. He thought the distribution of invagination of the bowel was very erratic. In Norway and Sweden this accident was very rare, while in Malmo and Copenhagen it was very common. Fifty to 60 per cent. of his cases were restored by manual treatment, such as massage and injections.

Braun and Madelung were surprised at these results, and instantly asked if 50 or 60 per cent. actually recovered without operative surgery, to which he replied in the affirmative. Was he sure he had diagnosed the cases aright as invagination? This he also affirmed was the case.

## Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, October 1st, 1904.

At the recent meeting of the Royal Hungarian Medical Society, Dr. Gaspar related his conclusions drawn from 125 cases of typhoid fever, in which the Widal test has been used.

1. The serum reaction may be obtained towards the end of the first week of typhoid fever, but is more usual later in the disease.

2. It may be present without a relapse at the end of the fourth month.

3. It may be absent one day and present the next.

4. Of 125 cases of typhoid fever the reaction was absent in only one case. In two cases it failed, but there was in each only one test, in one case on the twelfth, and in the other on the eighty-second day.

5. In nineteen cases of other diseases clearly uncomplicated by typhoid there was no reaction.

6. In a number of difficult and perplexing cases the serum test was of distinct service in establishing or correcting the diagnosis.

7. This test will probably prove itself a useful aid to clinical diagnosis, and especially in hospital practice.

Professor Herozel gave a *résumé* of the technique of pneumotomy. He avoids exploratory puncture, which he considers liable to infect the pleural cavity, and, in case the parietal and visceral pleura have not become adherent, liable to infect healthy lung tissue when the needle is withdrawn, and liable to cause severe hæmorrhage from puncture of large vessels. He does not practise it unless it is to be followed by pneumotomy, in which case the needle is used as a guide to the cavity to be opened.

The resection of the ribs should be free. He claims that the more extensively the lung is exposed, the easier does the examination in manipulation of the lung become, and the more rapidly will the cavity close and heal. One or two ribs are removed in the usual manner. Should three to four ribs be resected, a flap incision of the superjacent soft parts is the most satisfactory method.

After the resection, if the pleural surfaces are adherent, the operation becomes easier and safer. The retraction of the intercostal space on deep inspiration and the slight descent of the lower lung border noted before the operation, the speaker thinks, would indicate this. Sometimes after the resection of the ribs, the lung can be seen to slide up and down during respiration, as the intestine is seen through the unopened peritoneum. When adherent, the parietal pleura appears greyish-yellow, spotted with fat, thickened and dense to the touch. Finally, a fine needle pushed into the lung is adherent, and consequently fixed to the chest wall. A free lung would cause it to oscillate.

The attempts to produce this adhesion of the pleural surfaces by ignipuncture, electrolysis, cauterisation, chloride of zinc, and other methods have now been abandoned in favour of immediate union by suture. This, it is claimed, can be easily done by experienced operators, especially when the surface of the lung is exposed, and if it is forced into the wound by inspiration or coughing. The lung once fastened to the edges of the wound, its collapse or pneumothorax is avoided. The operation can now also be quickly finished.

As regards the pneumotomy in indurated, infiltrated, anæmic tissues, when the blood circulation is impeded, the lung can be satisfactorily opened with the scalpel, but since eventually the operator meets soft, healthy tissue, and is dealing with foul gangrenous tissue, in order to limit infection, the use of the Paquelin cautery is to be preferred.

The speaker considers that an anæsthetic is hardly necessary. He would not use ether. In an operation alluded to chloroform was used.

In regard to the results of operative treatment, Herozel claims to show that in ninety-one cases there was recovery in 60 or 61 per cent.

## The Operating Theatres.

### GUY'S HOSPITAL.

TWO CASES OF RENAL SURGERY.—Mr. CLEMENT LUCAS operated on a little boy, *æt.* 6, for pyo-nephrosis of the left kidney. The patient was passing a large quantity of pus in his urine, and had a temperature of 102°. The left kidney could be distinctly felt enlarged and fluctuating by bi-manual examination in the loin and the front of the abdomen. The trouble began by pain in passing water four years ago. At that time he was admitted into the hospital, and a stone removed from the bladder by supra-pubic lithotomy. The boy

was re-admitted two years later for a perinephritic abscess situated in the right loin. This was opened and drained, but its immediate cause was not at the time ascertained. The abscess healed after a time, and the patient was discharged in improved health. Since then, according to the mother, he has been wasting, and of late it had been noticed that his urine was very thick and had an unpleasant odour. Mr. Lucas diagnosed a distended pyo-nephrotic kidney on the left side, and cut down upon the left loin. After dividing the muscles and separating the perinephritic fat, an enlarged kidney came into view through which a number of pale cystic abscess pouches were visible. A small stone could be felt in the pelvis of the kidney. The pelvis was opened opposite this, and the stone removed with forceps. A quantity of exceedingly foetid pus then escaped, but the various abscess cavities failed to drain until Mr. Lucas, pushing his finger in various directions, opened their narrow orifices into the general nephritic pelvic cavity. The interior of the kidney and its various cavities were next washed out by repeated flushings with warm boric lotion until what returned was free from foetor. A large drainage-tube was fixed in the interior of the kidney so as to provide for continuous drainage till the organ had shrunk. Mr. Lucas said that in this case both kidneys appeared to have undergone suppuration as a result of ascending pyelitis consequent upon stone in the bladder. The right kidney discharged in all probability through the perinephritic abscess which occurred a year previously. The urgent condition for which the boy was admitted recently was due, Mr. Lucas considered, to the acute suppuration with distension going on in the left kidney, where a small phosphatic stone was discovered giving rise to obstruction, whilst acute bacterial infection was destroying the renal structure. The object of the operation, he pointed out, was to get free drainage of all abscess cavities within the organ by making them readily communicate with the distended pelvis. As the right kidney appeared to have recovered after discharging itself a year before, he hoped that by draining and disinfecting the left kidney and removing from it the obstructing stone, it might recover sufficiently to remain a useful organ. With a suppurating kidney, alkaline urine, and phosphatic stones, there was, he thought, always a question whether one may not be dealing with a tuberculous condition to which the stone is secondary.

As a result of the operation the boy's temperature immediately fell to normal and his general condition improved.

The second case was that of a man, *æt.* 27, who first came under Mr. Lucas' care a year previously. The patient had suffered from pain in the right lumbar region for fifteen years, but only on one occasion had had anything approaching a renal colic. For years he said there had been deposits in the urine, sometimes blood and pus in quantity. Röntgen rays failed to demonstrate a stone, and Mr. Lucas at that time said he was inclined to regard the case as one of tuberculous kidney. He explored the kidney through the loin and found large branching phosphatic calculi surrounded by pouches of pus of a very foetid character. The calculi were removed, the cavities washed out, and the kidney drained for a time, after which the wound was allowed to heal, and the patient left the hospital greatly relieved. In the spring of the present year, he began to be reminded again of his kidney by a recurrence of pain in

the right loin. Soon after, the deposit of pus, which, though greatly diminished, had never entirely disappeared, began to increase in quantity. The patient was re-admitted a week before the present operation, when the kidney could be distinctly felt to be considerably enlarged, and Mr. Lucas concluded that suppuration was still going on within it. As the man never had any pain in the other kidney, and as he passed a fairly good amount of urea by the normal passage at the time the kidney was drained a year before, and considering the extensive damage to renal structure discovered at the first operation, Mr. Lucas advised the patient to submit to excision of the kidney if at the time of the second operation the organ was found to be practically useless. At the operation an incision was made just above the level of the old scar in a transverse direction, and this was enlarged by a vertical incision corresponding to the anterior border of the quadratus lumborum. The capsule of the kidney was found to be closely adherent to the perinephritic fat and other structures, so that it would have been impossible to remove the kidney with its capsule. Mr. Lucas, therefore, first emptied the organ by puncturing it with a large cannula, then tore open the capsule, and stripped the kidney out from within the capsule till he reached the point where the fleshy substance became continuous with the pelvis and the main vessels. At this point the pedicle of the kidney was transfixed and ligatured, the substance of the organ being all cut away. Very little hæmorrhage took place during the operation. A large packing of cyanide gauze was used for drainage. Mr. Lucas said that the pathological examination of the kidney showed that the organ was tuberculous, although repeated examinations of the urine had failed to find any bacillus. The fact that the tubercle bacillus was at work in the kidney accounted, he thought, for the disease not clearing up after the complete extraction of the phosphatic stones fifteen months before. Thus the second operation, which comprised the removal of the kidney, brought the diagnosis back to that originally made before the extraction of the phosphatic stones, and it would seem that the formation of these stones was probably secondary to the tuberculous process causing alkalinity of the urine and precipitation of the phosphatic salts therefrom.

Since the operation the patient has progressed favourably and his temperature has remained normal.

#### Case of Bubonic Plague in the Tyne.

BUBONIC plague was last week reported to have broken out on board the London steamer, "Bishopsgate," which arrived in the Tyne from Hamburg, and was placed under strict observation. While the vessel was at Hamburg, discharging a cargo from Rosario, rats which had died from plague were found on board. At Jarrow it was necessary to remove to the floating hospital for infectious diseases the boatswain, a German, who only joined the vessel at Hamburg before she left for the Tyne, and a bacteriological examination made by Dr. Harker showed that the patient was suffering from bubonic plague. The "Bishopsgate" has been carefully disinfected and allowed to leave the Tyne, the remainder of the crew being found all well.

#### Harveian Society of London.

THE opening meeting of the seventy-fourth session of the Harveian Society of London will be held at 8.30 p.m., on Thursday, October 13th, at the Stafford Rooms, Titchborne Street, Edgware Road. Mr. C. B. Keetley will deliver the Harveian Lecture for the year, the subject being "Plastic Surgery."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 5, 1904.

### MR. CORONER TROUTBECK ON YOUNG SURGEONS.

THE position taken up by the London Coroner, Mr. Troutbeck, with regard to medical practitioners and their evidence generally may be characterised as unfortunate. Sooner or later it seems more than probable that his ill-advised tactics will lead to disastrous consequences, so far as the relations of the Coroner's Court, the public, and the medical profession are concerned. The leading principle which has guided Mr. Troutbeck, and upon which he has dilated in season or out of season, is the incompetency of the general practitioner. If any person dies of cerebral hæmorrhage, or of advanced heart disease, or from any other ordinary morbid condition, the medical practitioner who is certified as competent to attend to the health of our fellow-citizens during life is nevertheless incompetent, according to this sapient Coroner, to ascertain and certify the cause of their deaths. To tell us how they die demands the services of an expert "pathologist" (save the mark!), whose expertness is apparently to be decided by a standard fixed by Mr. Troutbeck. The gentleman singled out by the Coroner for that distinction deserves nothing but sympathy. He has been placed in a false position, whilst his services are utilised to deprive certain of his professional brethren of a considerable amount of legitimate medical practice. It was originally announced that Mr. Troutbeck's "expert" was to be called in at a special fee in difficult and obscure cases only. With that arrangement there would not have been much room for difference, as it is obvious the Coroner should have some latitude in his power of summoning highly-skilled aid under special circumstances. As a matter of fact, the simplest and most ordinary cases are placed daily in Dr. Freyberger's hands by Mr. Troutbeck. We have no hesitation

in asserting that in a large proportion of these cases equally good or better evidence could be furnished by local medical men, who in many instances have attended the deceased during life. There is little need, however, to discuss either the facts or the merits of the dispute that has arisen between Mr. Troutbeck and the medical profession. The whole matter has been investigated by a sub-committee of the British Medical Association, which has collected, sifted and arranged facts, evidence and conclusions with masterly precision. A correspondence with Mr. Troutbeck has simply evoked contemptuous defiance and evasion of issues, together with a flat denial of what appear to be incontrovertible statements. Nor has a further appeal of the committee to the Lord Chancellor, under whose jurisdiction the Coroners fall, produced any more satisfactory result. The next steps of the British Medical Association committee will be awaited with interest. If Mr. Troutbeck is unwise enough to declare war to the knife with the medical profession, he will most certainly raise issues of a far wider significance than those that appear on the surface. The machinery of the Coroner's Court is antiquated, and its procedure often slipshod and unsatisfactory to a degree. It is a question whether the whole system could not advantageously be replaced by a simpler court of official inquiry framed somewhat on the lines of those of the Procurator Fiscalship of Scotland. Meanwhile, nothing but harm can result from the unceasing flouts and jeers which Mr. Troutbeck sees fit to fling at the heads of all medical men except that of his pathologist, who is now openly announced as pathologist to the London County Council. The inner history of that appointment has not yet come to light, but it seems not unlikely that the policy of distrust of the general practitioner may one day be traced to one or more influential members of that body. If the Association committee want to get at the root of the matter, we should advise them to ascertain the attitude of medical members of the London County Council with regard to Coroners and to the appointment of Dr. Freyberger. The latest feat of Mr. Troutbeck has been to launch a particularly offensive attack against house surgeons generally. One of his jurymen not unnaturally asked why the evidence of a house surgeon had not been taken, whereupon the Coroner explained that the testimony of such persons was of little value. The dispute between the profession and Mr. Troutbeck has now been going on for a long time. Remonstrances and arguments have been of no avail, as that gentleman now clearly shows by fastening a gratuitous insult upon the large class of resident medical officers, many of whom are highly qualified and brilliant men. The time is come for legislative interference in the relations of the Coroner's Court and the medical profession. The situation has grown intolerable. In the long run it may be that the thanks of medical men, as well as of the general public, will be due to Mr. Coroner Troutbeck for the persistent way in which

he has forced the flaws and the potential powers of maladministration of the Coroners Acts upon the public attention.

#### CHRONIC CASES IN HOSPITAL WARDS.

THE question of the suitability of individual cases for admission as in-patients to hospitals requires the exercise of a good deal of judgment about the exercise of which evidently exists some misconception in the minds of those who are responsible. The two chief factors which influence the decision are, first, the urgency of the case; and, secondly, the in-patient capacity of the hospital. Every resident medical officer knows, or should know, that he is perfectly justified in temporarily exceeding the bed-accommodation at his disposal in times of emergency. Overcrowding of hospital wards is, of course, an evil to be rightly avoided, but few medical superintendents will be found who would seriously object to go beyond the theoretical limit if, for example, a bad accident or a case demanding speedy operation required admission. Preference must always be given to acute cases, and the smaller the hospital the more necessary it is that this rule should be enforced. We have known of instances where serious accidents have been sent away from hospitals on the ground that there was no accommodation, whereas, if the truth were known, the beds were largely taken up by chronic cases, awaiting their discharge or the application of a long-delayed plaster splint. Mere slackness on the part of house-officers is neither the only nor the chief cause of the filling of beds by unsuitable cases. In some districts the subscriber's letter system has such power that a patient, armed with this document and suffering, it may be, from some trivial complaint, which could quite well be treated in the out-door department, is instantly admitted into one of the few vacant beds of which he or she takes triumphant possession, while the unfortunate individual, stricken by mortal sickness, but unprovided with such a passport, is wholly unable to find shelter. This is by no means an imaginary occurrence. In other cases, patients are admitted with lingering diseases, such as chronic phthisis, or incurable nervous affections, who would be better off in their own homes or in the Poor-law infirmaries, for it is obviously unfair to keep a single bed occupied for months in succession by a patient for whom little good can be done, when in the same space of time five or six acutely suffering ones might have been permanently cured by operation or otherwise. The whole question is of immense practical importance, both to the general public and also to the governing bodies of the hospitals themselves. Where there is a medical school attached to a hospital the "chronic case," considered in the abstract, has a definite part to play in clinical instruction, for it often happens that bedside teaching is impossible upon acute cases, either from the severity of the symptoms or because the patient is frequently admitted at night. Chronic cases, on account of the stationary or

slowly changing character of their physical signs, are particularly suitable for clinical examination by students, and a good teacher can always find some fresh point upon which to dilate when the regular ward visit takes place. But in hospitals without a medical school, where the number of beds is more or less limited, an intelligent selection of cases for in-patient treatment must be made, due consideration being paid both to the relative severity of the symptoms and also to the claims of the outside supporters of the institution. All suffering, chronic or acute, must be relieved, and how this can best be done with the greatest possible benefit to all is one of the problems which we are glad to think is, on the whole, being daily solved in our hospitals and infirmaries.

### Notes on Current Topics.

#### Dearth of Medical Men in Russia.

THE evils of a great war reach far beyond the battlefields on which the trial of strength is made. The penalties of suffering and death may be paid by innocent sufferers many thousands of miles away from the scene of action. Too often the bread-winners—fathers, sons, husbands and brothers—are called to fight the battles of their country, which does not always provide adequately for friends and relatives in case of death or disablement. Another way in which those left at home may indirectly suffer is in the dearth of medical men, of whom the flower is called away to every campaign. In the South African War even our own overcrowded medical profession was depleted to such an extent that the pinch was everywhere felt in the lack of stop gaps and of resident assistants and medical officers. At the present moment in Russia, where a war is being waged on a scale far surpassing our own South African campaign, the want of medical men in country districts is making itself most keenly felt. Thus a London newspaper reports that there is no one to fill up the gaps caused by medical men who have gone to the war. The usual possible candidates have themselves gone to Manchuria with the many field-hospitals that have been equipped by the Red Cross Society, the town councils, and other public bodies, and, in many instances, by private enterprise. The wicked waste and wantonness of war was never more cruelly shown than in these districts of rural Russia drained of their medical men. Under any circumstances it seems that the inhabitants of that country are destined for years to come to pay a toll of daily sacrifice for its attempts at foreign annexation.

#### Bacteriology of Pertussis.

CONSIDERING the easy field for study offered by whooping-cough it is a matter of some surprise that we are still without any decided knowledge as to the causative organism. It is a common disease in most countries, so that there is no lack of clinical material on which to work. Moreover, for generations it has been recognised as infectious, and no observation has thrown any doubt on this belief.

It has been established that the sputum may act as a vehicle of infection, although not perhaps the only one. In addition to these facts, all tending to bring the disease into the region of easy investigation, it is known that one attack confers immunity, a second attack in the same subject being extremely rare. In spite of all this, there is as yet no general agreement as to the nature and history of the organism at work. It is true the investigations have not been wanting, but the results, where there are any, are greatly at variance with each other. One of the most elaborate inquiries was that conducted some years ago by Czaplewski, who found in every case of a series of forty-nine a small bacillus resembling that described in connection with influenza. This bacillus he regarded as the cause of pertussis, although he was unable to obtain any experimental proof. More recently Manicatide has described a very similar bacillus which he found in sixty-seven out of eighty-two cases examined. It differs, however, from Czaplewski's bacillus in certain staining and cultural reactions. It, however, gives the agglutination reaction with serum from patients affected with whooping-cough, and an antiserum produced by inoculating sheep and horses is stated to have been of service in the treatment of the disease. It is possible that further inquiry may establish the identity of Czaplewski's and Manicatide's organisms, but at present the whole question is in a very unsettled condition.

#### Suprarenin in Surgical Operations.

THE great therapeutical use that was anticipated from animal extracts when they were introduced into practice some years ago has hardly been justified in the majority of instances, but in the case of supra-renal gland extract a powerful and valuable drug has been placed at our disposal. In fact, its full uses are probably not thoroughly grasped yet. A series of experiments by Müller (a) seems to show that, in surgery, it may lend invaluable aid in the performance of quite extensive operations by allowing them to be performed practically without loss of blood. Müller found that by previously injecting the parts to be cut with suprarenin solution, not only was the operation rendered far easier of performance for the surgeon, but also the amount of shock was diminished by averting the loss of blood. He experimented on animals, removing portions of the liver and the kidney, and performing excision of glands, rib-resection, and laryngectomy. No blood was lost if a sufficiently strong injection was given, and no toxic symptoms were noted. Suprarenin hydrochloride in salt solution was used in strengths varying from 1-1,000 to 1-10,000, and was freely injected into the site of the projected operation. Its vaso-constrictor effect was well marked in half a minute in the case of strong solutions, and in one or two minutes when the weaker ones were employed, Müller thinking that in man the most that it is advisable to give is 10

(a) *Muench. med. Woch.*, Nos. 5 and 6, 1904.

cubic centimetres of a 1 per cent. solution, but as this is sufficient to render all operations bloodless, no more could ever be wanted. We wonder if the surgery of the future is to be as free from blood as it is now free from pain, and if suprarenin is to be the agent. If so, the act will have lost its greatest present drawback, and no greater boon since the introduction of antiseptics will have been conferred on both operators and their patients.

#### Speech, Silence, and Bacteria.

THE world has been recently set agape by the published investigations of the Local Government Board into the subject of the sputtering forth of bacteria in the act of speaking. It was shown that in ordinary quiet speech bacteria were emitted only rarely. In all abnormal respiratory acts, however, such as speaking loudly, laughing, coughing, sneezing, and so on, these micro-organisms, with all their powers for good or for evil, were distributed right and left in wholesale fashion. In some instances, indeed, we are told they were traced to a distance of forty feet. It is just as well to remind our readers that the whole subject was dealt with some time ago by Dr. Mendès de Léon, of Amsterdam, who showed experimentally that many micro-organisms were expelled from the mouth in particles of saliva expelled by the act of speaking. He drew the attention of the British Gynaecological Society to the danger of the contamination of open abdominal wounds in this way by the operator speaking to bystanders. The practical outcome of his work was a mask devised to prevent the particular risk in question. The article was published at the time in *THE MEDICAL PRESS AND CIRCULAR* (January 27th, 1904). An editorial comment on Dr. De Léon's researches appeared at the time under the heading of "Silent Surgeons." Our remarks had a wide circulation at the time among the lay newspapers. It is to be hoped they will give equal publicity to the fact that the honour of the original discovery is due to a distinguished surgeon of Amsterdam.

#### Pepper as a Dressing for Wounds.

IT is never wise to dismiss popular notions as nonsense without careful critical examination. There is no smoke without fire, and it often happens that man finds out the right thing by rule of thumb generations, or it may be centuries, before the light of exact science is available. Take the instance of pepper as a dressing for wounds in the rough and ready veterinary surgery of the farm and the stable and streets. The carman who borrows a pepper-pot from the nearest public-house and liberally bestrews with pepper the cut on his horse's knee wots nothing and cares less that the essential oil of pepper is a strong aromatic and stimulant antiseptic. He knows, however, that the wound will heal quickly under that treatment, and that is enough for him. There is not the least ground for supposing that pepper is a painful dressing for a wound, indeed, anyone who cares to try it on a cut finger will find it infinitely less

painful than a score of other things used for the same purpose. But, forsooth, because it is a strong stimulant to the tongue certain wiseacres are apt to imagine that it must be equally powerful when applied to cut tissues, forgetting, or not knowing, the differing response to stimulation of nerves of special and of ordinary sense. Acting on this nonsensical view, some magistrates actually sent to prison for several weeks an unfortunate man who peppered a horse's wounds. The so-called cruelty was a rough kind of antiseptic surgery. The sentence in question was barbarous, inane, ridiculous, and absolutely unworthy of the spirit of the present scientific age, which clearly has not yet permeated the magisterial bench of the kingdom.

#### Toxins and the Eye.

AS might be expected, the conjunctival surface, like the rest of the surface of the body, has a rich bacterial flora. Among the commoner bacteria present are the staphylococcus aureus and the micrococcus lanceolatus. While these or other bacteria are present in small numbers, or on the surface of the eye, no inflammation results, so that it is evident that they do not cause inflammation simply by acting as foreign bodies. Inflammation can be caused by certain bacteria alone, and that only after a certain period of exposure to them has taken place. It is probable, then, that the action of bacteria on the eye is due to the production by them of certain toxins, and this occurs only when the organisms are in, and not merely on, the conjunctiva. Experiments with the toxins of the bacteria which are known to affect the eye bear out this conclusion. Randolph of Johns Hopkins Hospital, who has devoted much time to the subject, was unable to produce any injury by the mere instillation of bacterial toxins into the conjunctival sac, even with several hours' contact. On the other hand, the same toxins when injected into the tissues of the eye produced marked changes, varying in kind and degree with the bacterial source of the toxin employed. An interesting practical point is that the presence of even virulent bacteria on the conjunctiva is probably harmless, so long as the covering membrane remains intact.

#### Alcoholism and Insanity.

THERE is no class of disease of whose causation we are more ignorant, and in which the public take more interest, than those of the mind. And, indeed, there is no more difficult task than for an alienist to pick out from an imperfectly-known and often deliberately misleading personal history, taken in conjunction with a still less known original constitution, some one factor or habit and label it alone as the cause. It is the entire group of antecedent conditions which is in truth the cause of anything, as Mill long ago insisted, and in the case of disease, and especially of disease of the mind, is this particularly to be remembered. In the selection of one of these conditions and the setting it up as the cause, there is, when the group of conditions is large, ill-defined, and imperfectly

known, a great latitude given for individual bias. In the classification of the causes of insanity, for instance, no two observers would be likely to return the same table for any hundred patients. This being so, we are not surprised that Dr. Clouston's opinions recently put forward as to the prominence of alcoholism as a cause of insanity have not received quite the respect which is due to any observation by that distinguished alienist. His judgment that in 42·3 per cent. of the male patients in the Royal Edinburgh Asylum last year drink was the cause of their condition is in marked contrast to the figures of other observers. Thus the average throughout the English asylums is returned as 16 per cent., though on the other hand Dr. Conolly Norman, of the Richmond Asylum in Dublin, approaches Dr. Clouston's views. It is very noticeable and strongly in support of their opinion that in the special form of insanity known as "alcoholic," about whose diagnosis there is no mistake, there has been a decided increase in recent years. At the same time it is not necessary to assume that drinking habits are actually on the increase. It would explain the facts, if in truth they are facts, equally well to hold that there is a diminished resistance on the part of the organism to alcoholic poisoning. We are inclined, indeed, to think that in many cases the alcoholism is primarily a symptom of the mental weakness which it in turn increases.

#### Australian Surgery Thirty Years Ago.

THE present generation of medical men find it next to impossible to draw a picture of the conditions which obtained in surgical work in the early seventies. We have grown up so completely in the age of anæsthesia and asepsis that we find it hard to realise that there was a time when these were not, and we are always interested to hear the pre-revolution reminiscences of our seniors. Dr. Melville Jay, of Adelaide, gives us in a recent address (a) an interesting sketch of what surgical work was like in the Southern Hemisphere when he began his professional life more than thirty years ago. Though anæsthesia was, of course, at that time the common practice, yet it was regarded as by no means a necessary adjunct to operations. Dr. Jay saw one unfortunate patient who, within a few days, suffered amputation of a leg and enucleation of an eye without any attempt to numb his sensibility. In the early seventies chloroform was the favourite anæsthetic used in Australia, but in 1875, following on the occurrence of some deaths under chloroform, an exhaustive inquiry was made by Dr. Thomas on the relative advantages of ether and chloroform. As a result it was made obligatory by the governing body of the Adelaide Hospital that ether should be the anæsthetic used when possible. After thirty years' experience, Dr. Jay finds the decision amply justified, and he has never seen a serious result attributable to ether anæsthesia. In the operating theatre it was unusual for the surgeon to wash his hands before operating, though he usually did so

(a) *Australasian Med. Gazette*, July 20th, 1904.

afterwards. It was the custom for him to wear a frock coat throughout, and the more numerous the blood-stains thereon, the prouder he was. Ligatures were always left long and hanging from the wound, and great pains were taken in learning the exact amount of force which should be employed in removing them later without bringing on secondary hæmorrhage. It was the duty of the house surgeon each day to pull on the ligatures until one by one they came away. In the treatment of dislocations use was made of a complicated and powerful system of pulleys, and in 1873 the thumb of a young man was all but torn from his hand by this apparatus. It is hardly matter for wonder that cases of pyæmia, septicæmia, erysipelas, and hospital gangrene were common in the surgical wards.

#### The Effect of Smoking Upon the Throat.

ONE of the evils resulting from the excessive or, in some cases, even the moderate use of tobacco is its peculiar effect upon the pharyngeal mucous membrane. The exact nature of the pathological processes which may follow too great indulgence in smoking is not always easy to determine since these are by no means constant. Then different laryngologists or throat specialists would, in all probability, give as many different theories as to the manner in which the fragrant weed may prove injurious to the pharynx and upper air passages. Definite teaching upon this point is most desirable, for the subject appeals with force to singers, speakers, and many others whose vocal organs are being constantly exercised. The so-called "clergyman's sore throat" is always supposed to be aggravated by smoking, but no one will assert that this is a common or a chief cause of chronic pharyngitis, which occurs in those of nervous temperament too frequently to be merely accidental. A recent analysis of tobacco smoke from cigarettes shows that there are 410 c.c. of carbon monoxide per 100 grammes, and it is the opinion of experts that it is this gas and not nicotine which does the greatest amount of harm. This was the view taken by Dr. S. W. Langmaid, of Boston, at a discussion upon the subject before the annual meeting of the American Laryngological Society, who stated that the quantity of nicotine carried to the throat was really very small as compared with the amount of carbon monoxide which was absorbed into the system and then produces vaso-motor disturbances in the pharynx. Singers with voices of low register appear to be less affected by smoking than those whose voice is of a higher pitch.

#### Temperance Lectures in Schools.

THE sympathetic hearing given by Lord Londonderry the other day to the deputation of the medical profession that waited on him to urge the importance of teaching hygienic and cognate subjects in elementary schools has not yet borne practical fruit. One of the points most strongly insisted on by the speakers of the deputation was the good likely to accrue to the rising generation by clearly setting before them at an early stage of their career

the moral and physical dangers of alcohol. It seems that in the Cheshire schools such instruction has been given for some years, and the County Education Committee when it was formed passed a resolution that these lectures should be continued. Unfortunately, teaching in such subjects is not included in the school curriculum mapped out by the seers of Whitehall, and the Government Inspector has been obliged to point out to the Committee that the Board of Education have consistently refused to recognise lectures on alcohol and temperance as fit subjects for inclusion in the school time-table. Dr. Hodgson, however, seems to have been equal to the occasion, for he proposed that the lectures should be given as object-lessons in elementary science, and moved the Committee to take on their own shoulders the responsibility of the lectures, so that the local managers might not be exposed to continual wrangles with the inspectors. The County Committee adopted the motion by a large majority, and as they are the authority for secular education the matter seems to be well within their province. Undoubtedly the study of inebriety and alcoholism is a "science," though, perhaps, one that is hardly contemplated by the syllabus of the Education Board, and as such may be taught; but we wonder where the object-lessons are to come from. Will the local public-houses be laid under contribution? Or will the teacher merely simulate the symptoms of intoxication? We hope, at all events, the Cheshire Committee will win their fight, and these useful lectures be continued.

#### City Orthopædic Hospital.

THE position that the City Orthopædic Hospital finds itself placed in is an embarrassing and anomalous one. The Metropolitan Hospital Sunday Fund have refused it their annual grant because the Governors of the institution continue to oppose the amalgamation of their hospital with others that call for a similar class of case; there has been no reflection on the management or treatment of patients; the question is purely one of policy. On the other hand, a good deal of sympathy, implied and expressed, has been shown by people who have taken interest in the hospital in the past, and by new friends whom they have won over to the cause. A scheme for placing the City Orthopædic on a footing that will render it independent of the Hospital Sunday Fund is now on foot, and there seems some prospect of success being attained. Without expressing an opinion on the merits of this particular question, one may point to this incident as an example of the necessity of some central body, such as the King Edward VII. Hospital Fund for London, definitely taking on its shoulders the onerous, invidious, but necessary task of deciding by public inquiry all questions of hospital policy and administration. As we have before pointed out, the King's Fund is in an immensely strong financial position with its income of £100,000, and it can command the services of the best talent, lay and medical, for work of this kind. It is neither fair to individual hospitals nor to the

public that these questions should be made foot-balls of in the columns of the daily Press. They are capable of definite solution if taken in hand by an authoritative body, and the committee of the King's Fund is obviously the right body for the purpose. Only all its proceedings should be carried out in the full light of publicity. We propose to allude in an early issue to the action of the Fund with regard to the sale of the site of the Royal Orthopædic Hospital under the chairmanship of Mr. Harry H. Marks, and its amalgamation with the National Orthopædic Hospital.

#### Radium Rays in Diphtheria.

It is, of course, only right that any substance that shows promise of being of service in the treatment of disease should be fully investigated therapeutically, but it must be confessed that experience gained in the applicability and utility of radium has not fulfilled all the hopes that were entertained when the metal was first discovered. There may still be disease conditions in which radium rays will prove themselves superior to those of Röntgen and Finsen, but it would seem from some careful researches carried out by Professor Prescott at the Massachusetts Institute of Technology that radium has little, if any, germicidal power. Experiments were made on the destructive effects of radium rays on micro-organisms in such widely differing resistances as *Bacillus coli*, *Bacillus diphtheriæ*, and *Saccharomyces cerevisiæ*, all of which were exposed for varying periods up to ninety minutes. None of these bacteria seemed to be much affected by the emanations, and Professor Prescott thinks that on whatever grounds radium rays may be useful in disease, it is not on that of the bactericidal properties. Other observers have claimed that two days' exposure will kill *Bacillus typhosus* and anthrax spores, but such a lengthened period of application is hardly possible in the treatment of patients, especially as the rays have shown that they can set up inflammatory or destructive changes in the tissues. Professor Prescott asserts that radium is certainly not adapted to the treatment of diphtheria, and that it should not be allowed to take the place of anti-toxin. The fringe of the possibilities of radium is yet only reached, but one is glad of definite evidence, even when negative, as to its ascertained potentialities and limitations.

#### The Journal "Public Opinion" and the Hospitals.

THE rejuvenation of an old-standing London journal—*Public Opinion*, to wit—has resulted in a number of the more or less familiar advertisement schemes that characterise modern journalism. As a medical journal we are concerned only with one of them—namely, a plan to benefit the hospital by prize competitions. Prizes to the extent of several thousand pounds, divided into sums varying from £200 downwards, are offered to those who collect and send in the largest sums to the office of the weekly journal above mentioned. There is not the slightest attempt to disguise or conceal

the fact that 25 per cent. of the money thus contributed will be appropriated for prizes and the necessary outlay. As pointed out by the editor of *Truth*, who has taken the matter vigorously in hand, the commercial nature of this journalistic venture is self-evident. The nature of the scheme, at any rate, is openly declared; and there can be little doubt that many medical charities spend at least 25 per cent. of income in the machinery of collection. It would be interesting to learn what is the precise proportion of income spent upon collection and upon administration by the London Hospital Saturday and Sunday Funds and, above all, by the Charity Organisation Society. We cannot, however, approve of the enterprise of *Public Opinion* in the present instance. Unfortunately, there are many axes in the hands of servants, tradesmen, landlords, and philanthropists that are daily ground at the expense of our medical charities.

#### The Supply of Drugs to Irish Unions.

THE question of the supply of drugs to Irish Unions is again assuming importance. It will be remembered that some years ago rather startling facts were elicited as to the methods in vogue for obtaining contracts. The method of tendering suggested by Dr. Stafford, a member of the Local Government Board, was then adopted, with eminently satisfactory results for a time. It now transpires, however, that many of the leading firms of wholesale chemists in Ireland have ceased to tender because it is impossible for them to compete with the prices quoted by others. In many cases, rebates are offered on the official price list as much as 37 and 40 per cent., with the result that many articles are supplied below their cost price. It is suggested that the Local Government Board intend to hold an inquiry into the causes which have caused leading Irish firms to cease tendering; but inasmuch as it is admitted that the Unions are receiving good drugs at a lower price than they ever did before, we doubt that the Board will consider itself called upon to interfere.

#### Bedding and Disease.

THE fitness of the bedding upon which we lie and with which we cover ourselves at night has an important bearing, not only upon the character of the sleep but also upon the general health, and it is accordingly not less worthy of attention than other matters concerned in the hygiene of the bed-chamber. The cause of the unrefreshed feeling which many people experience on rising in the morning is not always due to deficient ventilation. The necessity for pure air in the sleeping apartment is gradually becoming more recognised by the public, but the voice of the health lecturer has not hitherto been specially uplifted with regard to the quality and quantity of the bedding itself. To heap up blankets, coverlets, and rugs does not confer, in reality, any greater warmth than two or three light coverings of suitable texture, as, for instance, a sheet, blanket and eider-down quilt, while it is frequently productive

of the heavy, unrefreshing sleep of which so many complain. The old-fashioned, but extremely unhealthy habit of sleeping in the same garment next the skin which has been worn during the day is still rife among those who have, or think they have, a tendency to rheumatism, and any suggestion as to discontinuing this unpleasant custom is apt to be resented. The same curious conservatism is shown with regard to the feather-bed, which is a crafty device contrived to absorb a maximum of the organic matter thrown off by sleeping. Lying upon hard beds has cured many complaints of a congestive character, and the modern spring-mattress is capable of being purified with greater ease and at less expense than its older rival. The wool flock contained within the mattress is undoubtedly a possible source of danger to health, as has been recently pointed out by a sanitary inspector in Glasgow, who stated that analyses of this material in many cases compared unfavourably with ordinary sewage! Efficient sterilisation by heat should, however, suffice to render the wool flock perfectly innocuous as a material for bedding which, on account of its cheapness, is almost universally used.

#### Progeries and Senilism.

It is not long since our knowledge respecting the conditions which lead to that variety of physical immaturity known as infantilism was considerably enriched by the able and lucid description of a series of cases by Mr. Hastings Gifford. The same observer, in a valuable communication to the *Practitioner*, has described a peculiar condition of retarded development combined with premature old age, to which he gives the very appropriate name of "progeries" (*Gr progeros*), prematurely old). Three cases are narrated which died at the ages of seventeen, eighteen, and forty-three, respectively. The patients were all like children in stature, but of a peculiar wizened appearance, and possessed a wrinkled, atrophic skin. In intellectual power they were somewhat precocious, but otherwise the physical functions were normally performed. Mr. Gifford defines the condition as one of "infantilism upon which has descended the blight of premature old age," and in this connection it is interesting to observe that at the post-mortem upon the first case atheromatous changes were found with commencing calcareous degeneration in the coronary arteries and upon the valves of the left side of the heart. Premature senility alone is of frequent occurrence, but when it is found in conjunction with infantilism the result is pathologically most incongruous.

LIEUTENANT-COLONEL E. M. WILSON, C.B., C.M.S., D.S.O., recently retired, since his appointment as surgeon in 1881 has seen active service in the following campaigns: Soudan, 1884-85 (medal with clasp and Khedive's bronze star); Soudan Frontier Field Force, 1885-86; expedition up the Gambia, 1891-92; Ashanti expedition, 1895-96; Nile expedition, 1898 (mentioned in despatches; appointed D.S.O. and medals). Before this

record he served in 1879 as civil surgeon in the Zulu War (medal and clasp).

#### PERSONAL.

HIS MAJESTY THE KING has graciously approved the appointment of Lieutenant-Colonel Richard Philip Smart, Chief Government Medical Officer and Superintendent of Public Health of the Island of Malta, to be a member of the Executive Council and an official member of the Council of the Government of that island.

THEIR Royal Highnesses Prince and Princess Henry of Prussia have shown their sympathy with the work of the London Royal Waterloo Hospital for Children and Women by a letter of sympathy and an annual subscription of five guineas.

FLEET-SURGEON J. C. DOW, M.B., has retired from active service with the honorary rank of Deputy-Inspector-General.

DR. J. B. HOGG, Inspector of Asylums in Queensland, in his annual report recently presented to the Houses of Parliament, points out that the proportion of insane to the general population is steadily increasing in all the Australian States, and in a ratio greater than that of the United Kingdom.

THE Harveian Lecture will be delivered on Thursday evening, October 13th, by Mr. C. B. Keetley, on "Plastic Surgery."

MR. C. M. TUKE will deliver the Presidential Address of the 23rd Session of the West London Medico-Chirurgical Society on Friday evening, October 7th, upon the subject "Progress in Psychology."

SIR JAMES RECKITT, of Hull, has generously offered to double the amount of the Hospital Sunday Fund collected in that town, after the first thousand pounds have been reached.

DR. E. SYMES THOMPSON will deliver a course of four lectures on "Evolution in the Vegetable Kingdom" on October 4th and the three following days, at Gresham College, London, at 6 p.m. each day.

ON October 20th, Lord and Lady Rothschild will open the administrative buildings of the Epileptic Colony at Chalfont of the National Society for the Employment of Epileptics.

DR. CHAMBERS will entertain members of the South-Eastern Division of the Medico-Psychological Association at luncheon, at the Priory, Roehampton, London, S.W., on Thursday, October 6th.

DR. R. MURRAY LESLIE is the new President of the North-East London Clinical Society, of which the present winter session will be inaugurated by an address on October 6th by Sir R. Douglas Powell on "Antiseptic Principles in Medicine."

LIEUT.-COLONEL P. M. ELLIS, now commanding the 9th Company of the Royal Army Medical Corps at Colchester, has been appointed Principal Medical Officer of the 7th Division, 3rd Army Corps, at the Curragh.

DR. HENRY ASHBY, of Manchester, will deliver the Wightman Lecture of the Society for the Study of Diseases in Children in May, 1905.

It is officially announced that the Emperor of Germany has acceded to the request of Professor Dr. Robert Koch to be relieved of his post of Director of the Institute for Infectious Diseases, with a retiring pension. Notwithstanding his resignation, it is understood that Dr. Koch will remain in the service of the

State for purposes of research work, and in the course of the coming winter he will proceed to German East Africa to carry out certain bacteriological studies there.

DR. WILLIAM MARTIN, for over forty years physician to Jervis Street Hospital, Dublin, has, we understand, tendered his resignation.

DR. BRIEN O'BRIEN has been appointed medical officer to the Irish Constabulary of the Belfast District, in succession to Dr. W. B. McQuitty.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

#### BELFAST.

ULSTER MEDICAL SOCIETY.—A special meeting of this Society was held last week to elect a President for the ensuing two years in place of Professor Lorrain Smith, who was elected at the annual meeting in June, but who has resigned his post on leaving Belfast for Manchester. Dr. William Calwell was unanimously elected to the post, and as he has been for a number of years one of the most active members of the Society, frequently reading papers and showing cases, there is no doubt that the Society will flourish under his rule. The winter session will open in November, and it is expected that the bust of Sir William Whitla will be unveiled at an early date in the session.

THE SMALL-POX OUTBREAK.—After an interval of several weeks, in which it seemed to have been stamped out, small-pox has appeared at two different parts of the city last week, a man and a child being affected. Both were, of course, removed at once to the hospital at Purdysburn, where the man has died. The families in both cases have been isolated at the intercepting hospital at Twin Island. One or two cases have occurred in the country towns of Ulster during the week, but active measures are being taken everywhere the disease appears, and there is every reason to hope that it will soon be entirely stamped out.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

#### WHAT IS "INSANITY" ?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The interesting table talk which Dr. Robert Lee describes as having taken place at the house of the late Dr. Forbes Winslow, and at which the deceased gentleman is represented as having expressed the opinion "that nearly all the world was insane," appears to me to afford admirable corroboration of my contention as to the necessity of a legal or practical definition of insanity.

A short period ago I ventured to define insanity in its comprehensive or theoretical sense as "a greater or less deviation from reason," which definition would, of course, embrace superstitious and imaginary ideas treated as realities but unsupported by generally accepted evidence. Now I apprehend Dr. Forbes Winslow gave vent to the opinion just recited as applied to those such as my definition would include. If my conjecture be correct, I venture to say there are numbers of observers of the human mind who would agree with the deceased gentleman. Why, therefore, should Dr. Lee regard the late gentleman's opinion as "very amusing" ? Further, if it be necessary in order to convey a meaning of insanity in its comprehensive aspect to formulate a definition—I do not assert it is—but assuming the necessity for argument's sake, how much more necessary must it be to define insanity in its legal or more contracted sense.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, September 29th, 1904.

## THE "MEDICAL REGISTER."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interests of the profession, may I ask you to be good enough to draw attention in an early issue to the importance to practitioners of keeping their addresses correct in the "Medical Register"?

The chief points to which I should like to call attention are:—(1) The Register should not be confused with the Medical Directory, as is so often done; changes should be notified to this office by practitioners themselves, and a post-card should be received in acknowledgment.

(2) This year circulars of inquiry have been sent to all practitioners whose names begin with letters from H to O inclusive, and who originally registered at the office of the Branch Council for England; any person whose name falls within those letters who has not received a circular should communicate with this office at once.

(3) Anyone who is doubtful whether his address is correct should inquire at the office without delay.

In past years you have kindly done your best to assist me in my efforts to save practitioners from the grave inconvenience of finding that their names do not appear upon the Register because of the impossibility of getting into communication with them, and I hope therefore that you will be good enough to continue to give me the benefit of your valuable assistance in the matter.

I am, Sir, yours truly,

H. E. ALLEN, Registrar.

General Council of Medical Education and Registration, 299 Oxford Street, London, W.  
September 26th, 1904.

## MR. CORONER TROUTBECK AND HOUSE SURGEONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is it not time that public opinion was educated as to the relationship of the coroner to the public? As an administrative servant, his duties are clearly defined, and, just as in the case of one of his Majesty's judges, should he persistently evade, exceed, or fall short of his statutory powers and instructions, he becomes amenable to the higher authorities. The Westminster coroner, Mr. Troutbeck, has, in the opinion of many persons, exceeded his powers by employing Dr. Freyberger. He has persistently flouted the general practitioner, whom he has replaced by a so-called "expert" pathologist. At a recent inquest he explained to the jury he had called Dr. Freyberger to give post-mortem evidence in place of the house-surgeon of a hospital because he mistrusted the evidence of a young house surgeon, "perhaps" only just qualified. Does Mr. Troutbeck—self-reliant man that he is—not know that post-mortems in hospitals are conducted by skilled pathologists, about whose scientific standing and experience there can be no question whatever?

I am, Sir, yours truly,

A WESTMINSTER VICTIM.

September 27th, 1904.

## THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have followed the discussion of this momentous question from the initiatory stage of Professor Taylor's address in your columns to the present with much interest, and in reading Dr. Woods Hutchinson's article in the last number of the *Contemporary Review*, it occurred to me that one or two passages therein might appropriately be transferred to your columns as embodying certain facts for the elucidation of points raised by some of your correspondents. In the article referred to, entitled "Animal Marriage," the writer points out that every form of conjugal union which the ingenuity of man has been able to devise can be found to exist in full perfection among the so-called lower animals. "From promiscuity, through union simply for the mating season, to polygamy, polyandry, and finally monogamy and monoandry,

every possible phase and form of the institution can be studied outside of the human species. The same results appear to have been reached by experiment here as in our own species—namely, that in proportion as the species rise in the scale of aggressiveness and intelligence, promiscuity or mere mating-season union tends to disappear, and either a lasting form of polygamy, or more frequently a fairly well settled form of monogamy, in many cases even lasting for life, is reached. The progress of the forms of combination of the sexes might be expressed in the statement that the accumulations of racial experience tend to show that by the production of a smaller number of offspring and the expenditure upon these of a greater amount of parental care, better results can be obtained in efficiency and capacity for survival.

"We have living examples of every possible stage of the solution of this problem, from the production of eggs by hundreds of thousands, as in the insects and the fishes, with absolutely no parental care and a loss from enemies of 95 per cent., through the intermediate types of mammals, with their broods of from six to a dozen members, and with an infant mortality of probably not more than 50 per cent., up to the highest mammals, including man, with but a single offspring at a birth and an infant mortality of 20 per cent. And we believe that almost every individual instance will be found to be explainable by conformity to this law, in so far as circumstances permit; each progressive organism giving the greater amount of care and protection to the young, and thus causing the race to grow and progress; while each retrogressive or degenerate organism gives a smaller amount of parental care than is necessary to maintain the race at its level."

Thus, according to Dr. Hutchinson, we have the voice of Nature proclaiming the fewer the better, not only for the individual, but for the community at large. But here comes in the eternal *if* to spoil the Malthusian chimera—the power of which is exemplified in everyday experience—that the members of large families are generally better citizens, more energetic and resourceful than the pampered ones and twos of limited liability.

I am, Sir, yours truly,

ONE PERSONALLY INTERESTED.

## Obituary.

## GEORGE CROKER, M.D. GLASG., F.R.C.S.I.

We regret to announce the death of Dr. George Croker, at his residence, Mount Pottinger, Belfast, on September 22nd. Dr. Croker was born in Wicklow, and studied at Glasgow, where he graduated M.D. in 1840 and four years later became a Fellow of the Royal College of Surgeons in Ireland. For a time he practised in the south of Ireland, but afterwards he became resident physician to the present Marquis of Downshire's grandfather. Later, he took up residence in Ballyhackamore, and acted as dispensary medical officer of No. 11 Castlereagh district. He leaves two sons and two daughters; one of his other sons, Dr. E. Croker, died when house physician of the Royal Victoria Hospital some years ago. Dr. Croker, who attained the age of 90 years, was greatly respected and had at one time a large practice.

## ARCHIBALD HAMILTON, M.D.

The death has taken place suddenly at Windermere of Dr. Archibald Hamilton, one of the oldest doctors in Westmoreland. He took his degree at Edinburgh University in 1861 and came to Windermere as an assistant to the late Dr. Cowes. Dr. Hamilton was a Conservative, and at one time president of the Windermere Conservative Association. His bright and humorous speeches are well remembered. He was a county magistrate and a member of the District Council. It was largely owing to his efforts that the purchase of the Queen's Park Recreation Grounds was effected. He was also one of the organisers of the Windermere Art Exhibition held last year.

MR. W. J. LE TALL, M.R.C.S.ENG., L.S.A.

WE regret to announce the death of Mr. William James Le Tall, who died recently at his residence, Hackenthorpe, after several weeks' illness. Deceased was the son of the late Dr. Benjamin Le Tall, of Newton Croft, for many years surgeon at Woodhouse. Deceased was medical practitioner for Woodhouse, but some years ago he retired, and lived at Hackenthorpe. He was 64 years of age, and had been connected with the Woodhouse branch of the Society of Friends practically all his life. He held the qualifications of M.R.C.S., L.S.A., which he took in the year 1862.

WILLIAM WHAMOND, M.D.GLASG., L.F.P.S.  
GLASG.

DR. WILLIAM WHAMOND, one of the oldest medical practitioners in Jarrow, has succumbed at his residence Balgownie, after a short illness. He qualified in 1862, and went to Jarrow forty years ago, and soon established a lucrative practice. In addition, he was the official inspector of boys at the large works on Tyneside, and attended personally to this branch of his labours to the last. The doctor was a Justice of the Peace for the borough, but seldom sat on the bench. Dr. Whamond was twice married, and leaves a widow and two young children.

BRIGADE-SURGEON EDWIN WILSON, M.R.C.S.E.

BRIGADE-SURGEON EDWIN WILSON died suddenly on the 27th ult., at Bray, aged 78. He became an M.R.C.S. Eng. in 1851, received his commission as assistant surgeon in May, 1855, rising to the rank of surgeon in 1868, and surgeon-major in 1873, and retired in 1884 with the honorary rank of brigade-surgeon. He served in the 71st Highlanders with the Central India Field Force under Sir Hugh Rose in 1858, and was present at the battles of Koonch and Golowlee, the capture of Calpee, the action of Morar, and the recapture of Gwalior. He was also in medical charge of the flying column which was sent in pursuit of Burgore Sing. For these services he received the medal with clasp.

### Literature.

CLINICAL DIAGNOSTIC BACTERIOLOGY. (c)

THIS book, it is stated in the preface, is intended for the many practitioners who have not had an opportunity of studying in a laboratory or who have not the necessary equipment for bacteriological work. For such persons, however, the seventy-six pages devoted to an examination of the acid-fast bacilli can have little practical value; and in the strictly clinical part of the work the methods recommended are in many cases of so delicate and elaborate a character as to necessitate a previous knowledge of bacteriological technique, and the apparatus of a well-equipped laboratory. The absence of exact directions as to the best methods of procuring specimens and packing and dispatching these by post is to be regretted. On the other hand, Dr. Coles' book will be found of the greatest service to those working in a well-appointed laboratory, especially to senior students and resident medical officers of hospitals, who have to do the daily bacteriological examination of morbid materials from the wards or post-mortem room. With few exceptions we have found the directions given to be trustworthy, and special attention has evidently been paid to methods of staining, although we doubt if there is anything to be gained in a work of this nature in multiplying these. For instance, six methods of staining the pneumococcus capsule are given, and six of staining the diphtheria bacillus. We differ from Dr. Coles when he states that in examining urine there is little advantage to be gained by obtaining the specimen by means of a catheter, and in urine and other body fluids we believe that far better results can be obtained by a high speed centrifuge than by any form of sedimentation glass. A valuable feature of the book is the list of authorities

(c) "Clinical Diagnostic Bacteriology, including Serum Diagnosis and Cyto-diagnosis." By Alfred C. Coles, M.D., D.Sc., F.R.S. Ed. Pp. 236. London: J. and A. Churchill.

given, and here the latest and most valuable work of the best British and foreign observers has been included. With regard to the tests by which it is proposed to distinguish between tubercle bacilli and other acid-fast varieties, these will no doubt be subjected to close examination in the immediate future, and if found trustworthy will be generally adopted. In our own experience we have met with two cases in which a mistaken diagnosis was made owing to the smegma bacillus being taken for the tubercle bacillus, and such cases are not uncommon. The investigation of this matter must, however, for the present rest in the hands of bacteriological experts. The chapter on cyto-diagnosis should be read by all, for this aid to diagnosis, based on the examination of the nature and variety of the cellular elements found in an exudation, has not been as fully employed in the past as it should have been.

### Laboratory Notes.

"TABLOID" LITHIUM CITRATE AND UROTROPINE, EFFERVESCENT.

MEDICAL men who wish to administer lithium citrate in conjunction with urotropine will find "Tabloid" Lithium Citrate and Urotropine, Effervescent, an excellent preparation for the purpose. It is manufactured by Messrs. Burroughs Wellcome, and each tabloid contains:—

Lithium citrate, gr. 5 (0.324 gm.).

Urotropine, gr. 3 (0.194 gm.).

Effervescent basis, q.s.

In most cases it is clearly desirable to administer a combination of this nature in a good draught of water, in such case the effervescent properties of this product will be found advantageous. The combined action of these drugs is likely to render the particular tabloid of special value in the case of gouty patients suffering from urinary complications.

KEPLER'S MALT EXTRACT, WITH HÆMOGLOBIN.

WE have examined a sample of this well-known preparation of malt extract, received from the manufacturers, Burroughs Wellcome and Co., and have proved the presence of hæmoglobin. It is claimed that by the administration of hæmoglobin the iron contained therein is presented in a readily assimilable form, and with this statement most medical men are agreed.

The malt extract is a good one and contains somewhat less moisture than we have found in similar specimens. The sample submitted to us is remarkably free from any caramelised taste, and its flavour is excellent. These points are of consequence as they render it convenient of administration to children and to invalids.

SERRAVALLO'S IRON AND CHINCHONA TONIC.

THIS tonic forms an admirable means of administering iron and the cinchona alkaloids in a palatable form. Unlike so many preparations which claim to contain an appreciable amount of iron, we find on analysis that this preparation really does contain a quantity likely to be of value in cases of anæmia, debility, chlorosis, &c. At the same time the alkaloids from the bark successfully mask the taste of the iron and add to the value of the preparation. The basis of the preparation is a wine of good quality, and we have pleasure in bringing this preparation before the notice of our readers. The London depot is at 45, Holborn Viaduct.

MILO FOOD.

THIS food is prepared by Henri Nestlé, Vevey, Switzerland (of condensed milk fame), with a basis of dessicated milk, as is shown by its containing on our analysis 7.8 per cent. of milk-fat and a proportionate amount of milk-sugar. The remaining parts of the

food consist of cane sugar and starch, a portion of which has been partly converted by the action of diastase.

While some authorities insist that no starch whatever shall form part of the food of children under nine months of age, the proportion here given cannot be objected to, and its presence together with the maltose and dextrine will serve to break up any curd that would otherwise be formed by milk that would in all probability be given with the food to young children. The mineral matter, 1.3 per cent., is of the proper nature, consisting mainly of the phosphates of calcium and potassium to furnish the salts required for the building up of the framework of growing children. The nitrogenous, or flesh-forming properties are present in due proportion (12.1 per cent.), and the food, when mixed with milk and water, yields a uniform liquid of a slightly sweet taste and agreeable flavour, such as would readily be taken by children. The pamphlet issued by the manufacturers contains an adequate and accurate description of the composition of the food and is deserving of the attention of medical men.

## Medical News.

### THE WELSH RAILWAY ACCIDENT.—A MEDICAL HERO.

THE terrible railway accident in Wales on Monday last, when four persons were killed and many injured, will be ever memorable in the medical world for the heroic conduct of a medical man. This gentleman, according to the description of one of the passengers, took the direction of affairs into his own hands and gave orders for the smashing of doors and the cutting of holes in the roofs of the broken carriages, in order to reach the injured. His purely medical aid was no less prompt and valuable. He is described as having "worked magnificently," and as having even torn up his coat to make bandages. Before going to press we have been unable to identify with certainty this gentleman, of whom the medical profession may well be proud, but presumably he was Dr. W. Philip Jones, of Wostenholme Road, Sheffield, who was among the slightly injured.

### Death of a Medical Man from Chloroform.

AN inquest was held in Liverpool last week concerning the death of Edward Lloyd Roberts, who was in practice as a doctor at Chester with his father. On Wednesday evening he engaged a room in a temperance hotel in Liverpool. The next morning an assistant in the hotel knocked at his door several times, and, failing to get any answer, called in the police, who forced open the door and found him lying on the bed, fully dressed. He had a handkerchief in his left hand near his mouth, and was dead. In his pockets were several bottles which had contained either chloroform or laudanum. Richard Mills, a brother-in-law, said that Dr. Roberts was a teetotaler, quite steady in his habits, and he had been in fairly good health. He had been addicted to the habit of taking chloroform for the last twenty years. He had told witness that while under the influence of chloroform he had beautiful dreams and that he took it very strong. He had tried, but unsuccessfully, to break off the habit. The chemists in Chester would not supply him with the drug, but he obtained it at shops where there were new assistants or in other towns. In Dr. Corlett's opinion death was due to chloroform poisoning by inhalation, and Detective-Inspector Robertson said that he had seen Dr. Roberts on Tuesday, and at that time he was quite satisfied that he had no intention of committing suicide. The jury returned a verdict of death from misadventure, and expressed deep sympathy with the family.

### St. Bartholomew's Hospital.

THE following are the results of the recent examinations:—*Senior Entrance Scholarships in Science* (value £75 each), E. P. Cumberbatch and G. Graham. *Junior Entrance Scholarship in Science* (value £150), T. S. Lukis. *Preliminary Scientific Exhibition* (value £50),

G. Rigby Lynn. *Jeaffreson Exhibition* (value £20), K. C. Bomford.

### London Hospital Medical College.—Entrance Scholarships.

*Science*, "Price" Scholarship (£120), Mr. A. H. Penistan; *Science Second* (£60) Scholarship, Mr. C. Ilderton Wright; *Science, Third* (£35) Scholarship, Mr. Ronald Candy; *Science, Hon. Certificate*, Mr. E. B. Morley. "Price" Scholarship in *Anatomy and Physiology* (£60), Mr. R. B. Lloyd, Emmanuel College, Cambridge. *Epsom Scholarship* (£120), Mr. J. P. Little.

### Middlesex Hospital Medical School.

THE following scholarships have been recently gained:—*First Entrance Scholarship* (£100), Mr. A. O. English. *Second Entrance Scholarship* (£60), Mr. P. S. B. Langton. *University Scholarship* (£60), Mr. E. L. Kennaway, B.A. Oxon. *Freer Lucas Scholarship* (£126), Mr. E. A. Saunders.

### University of Durham—Faculty of Medicine.

THE following candidates have satisfied the examiners:—

*M.B. (final).—Honours—Second Class.*—Neville Avory Eddlestone, and Richard Woodward Swayne. *Pass List.*—Vincent Edgar Badcock, Frederick William Cheese, M.R.C.S., L.R.C.P., John Bowman Cooke, George Denholm, Sampson George Victor Harris, Florence Barrie Lambert, Arthur Cecil Hays McCullagh, Frederick Charles Pybus, George Robert Philipson, Norman Spedding, Thomas Leathard Wormald.

*Second Examination.—Anatomy, Physiology, and Materia Medica. Honours—First Class.*—Herbert Max Levinson.

*Honours—Second Class.*—Edward Percival Hearne Joynt, Charles Gordon Kemp, Roland Wilfred Pearson, M.R.C.S., L.R.C.P.

*Pass List.*—Orrock Arnott, Harold Henry Blake, Frederick William Cheese, M.R.C.S., L.R.C.P., William Harold Edgar, George Reginald Ellis, John Everidge, John Ernest Hanna, Herbert Fletcher Joynt, Stanley Dunn Metcalfe, William Rollin, James Wilkie Smith, Leslie Henry Walker, George Walker, Lionel Langford Westrope.

*First Examination.—Elementary Anatomy and Biology, Chemistry and Physics.—Honours—First Class.*—Charles Frederick Morris Saint.

*Honours—Second Class.*—Henry Glendinning Davison.

*Pass List.*—Norman St. Clair Bruce Cummins, Percy Hall, Isaiah Hodgkinson, Herbert Richard McAleenan, Satyen Mozumder, Jack Dixon Turnbull.

### Odontological Society of Great Britain.

WE are asked to announce that the above Society is prepared to receive applications for grants in aid of the furtherance of scientific research in connection with dentistry. For particulars and forms of application apply to the hon. secretary, Scientific Research Committee, Odontological Society, 20 Hanover Square, W.

### King's College and King's College Hospital (University of London.)

THE following scholarships have been awarded in the Faculty of Medicine:—*Medical entrance*, £50, E. B. Clayton and A. F. Comyn, equal; *Sambrooke*, £100, B. Hughes; *Two Warneford*, £100 each, T. H. Whittington and G. Matthews; *Epsom Scholarship* (fee tuition), H. A. Milner.

### The Medico-Legal Society.

THE third annual general meeting of this Society will be held at 22 Albemarle Street, New Bond Street, London, W., on Tuesday next, October 11th, at 8.15 p.m., when the reports of the treasurer and the secretaries will be presented, the officers for the coming session elected, and the following resolutions moved:—

(a) By Dr. W. Wynn Westcott, "That this Society shall be called the 'Medico-Legal Society of Great Britain and Ireland.'" (b) By Dr. F. J. Smith, "That the annual subscription shall be one guinea, and that a composition life subscription be fixed." (c) By Mr. R. Henslowe Wellington, "That the rule *re* the Presidency be rescinded, so that the office may be held for three consecutive years."

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**"THROAT CASE"** (Bedford).—A correspondent from Bedford has sent us what evidently is a clinical record of an anomalous case of diphtheria. Unfortunately a portion of the MS. has been lost in the post, and the only clue to its origin is the postmark on the envelope. We should be glad to have a further copy with the name and address of the sender.

### THE POOR MAN'S CHILD.

A DISTRICT nurse was sent to see a poor young patient, and wishing to examine the child and thinking a wash desirable, she asked the mother if she had a bath. "Lor, yuss, nuss," was the answer: "we've 'ad a bath in the 'ouse these seven years; but, thank God, we've never 'ad to use it!" Further inquiries elicited that the bath was regarded as medicinal, and only to be taken under doctor's orders!—"Our Hospitals and Charities Illustrated" (Kegan Paul).

J. W. E. (Reading).—It is against our rule to discuss medical subjects with lay correspondents. The Finsen treatment undoubtedly cures some cases of lupus, but for others it compares unfavourably with ordinary surgical measures. A full answer to your questions could be obtained by means of an ordinary consultation.

### THE DOCTOR ORDERED A TONIC.

MAGISTRATE to Paddy:—"I see you were arrested for stealing a grate"

Paddy:—"Sure, an' it was the docthor's fault, he towld me to take iron, and didn't I follow his advice and take a stove, bad luck to him!"

**EDINBURGH.**—The proposition that uric acid met with in man is conveyed to his tissues mainly by means of flesh, eaten as food, cannot be taken as established. The facts of avian physiology will have first to be clearly explained, to say nothing of many phenomena concerning natural and morbid uric acid formation in man. At the same time the arguments both *pro* and *con* are worthy of most careful consideration.

### PREVENTION OF CRUELTY TO CHILDREN.

THE Act of 1894 having been found during the ten years working to be defective and difficult of application, an amended Act was passed during the last Session and became law on Saturday last, October 1st. The principal Amendment aims at the suppression of the iniquitous customs of insurance of infant life, whereby the insurer gains a money premium on the death of the child. The *bona fides* of transactions of this nature will need such convincing proofs in future that it will be morally impossible for the guilty to profit by this form of so called cruelty—imprisonment being the more likely alternative.

**WEST TOWN (Berks.).**—The number is out of print—you will find the reference in any medical library.

D. P. H.—The fallacy of a low general death-rate which disguises a high infantile mortality is obvious. We are obliged for drawing our attention to the point and accept with pleasure your offer of a paper on infantile mortality generally.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, OCTOBER 5th.

**OBSTETRICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Lockyer, Dr. Handfield-Jones, and others. Paper.—Dr. J. M. Kerr: Certain Details regarding the Operation of Cesarean Section in Cases of Contracted Pelvis, based upon a Series of 30 Cases.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. P. J. Freyer: Clinique. (Surgical.)

### THURSDAY, OCTOBER 6th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.)

### FRIDAY, OCTOBER 13th.

**HARVEIAN SOCIETY OF LONDON** (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Harveian Lecture Mr. C. B. Keetley on "Plastic Surgery."

## Vacancies.

**City Hospital for Infectious Diseases, Newcastle-upon-Tyne.**—Resident Medical Officer. Salary £100 per annum, with board, lodging, &c. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

**Wolverhampton and Staffordshire General Hospital.**—House Physician. Salary £100 per annum, with board, lodging, and washing. Applications to Edmund Forster, House Governor and Secretary.

**Royal Victoria Hospital, Dover.**—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Arthur B. Elwin, Esq., 2 Castle Street, Dover.

**Royal Hospital for Diseases of the Chest, City Road, E.C.**—Resident Medical Officer. Salary £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary.

**Brecon and Radnor Lunatic Asylum, Talgarh, Breconshire.**—Medical Superintendent. Salary £450 per annum, with fully furnished house, coal, light, washing, and garden produce. Applications to J. H. Evans.

**Northampton General Hospital.**—House Surgeon. Salary £100 per annum, with furnished apartments, board, attendance, and washing. Applications to C. S. Bisbee, Secretary-Superintendent.

**County Asylum, Mickleover, Derby.**—Senior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

**Leicester Infirmary.**—Assistant House Surgeon. Salary £80 per annum, with board, apartments and washing. Applications to the Secretary.

**Essex County Asylum, Brentwood.**—Assistant Medical Officer. Salary £150 per annum, with board, and residence. Applications to the Medical Superintendent.

## Appointments.

ANDERSON, C. A., Junior House Physician to St. Bartholomew's Hospital.

BIRKETT, H. J. D., Junior House Surgeon to St. Bartholomew's Hospital.

BOWEN, M. W., Surgeon to the Royal Ear Hospital, Soho, W.

BOYLE, H. E. G., L.R.C.P.Lond., M.R.C.S.Eng., Assistant Chloroformist to St. Bartholomew's Hospital.

BREWERTON, E. W., F.R.C.S.Eng., Clinical Assistant to the Department for Diseases of the Eye, St. Bartholomew's Hospital.

BURFIELD, J., Junior House Surgeon to St. Bartholomew's Hospital.

BURROUGHS, H. N., Senior House Surgeon to St. Bartholomew's Hospital.

COCKE, M. STURGEON, M.E.C.S., L.R.C.P.Lond., Assistant Surgeon to the Royal Ear Hospital, Soho, W.

COLEMAN, F., M.R.C.S., L.D.S., Clinical Assistant to the Dental Department, St. Bartholomew's Hospital.

COLT, G. H., Junior House Surgeon to St. Bartholomew's Hospital.

CRIPPS, L., Junior House Surgeon to St. Bartholomew's Hospital.

GASK, G. E., F.R.C.S.Eng., Clinical Assistant to the Department of Orthopaedics, St. Bartholomew's Hospital.

GOULD, H. A., Resident Midwifery Assistant at St. Bartholomew's Hospital.

HADFIELD, C. F., Junior House Physician to St. Bartholomew's Hospital.

HAGGARD, T. B. A., M.R.C.S.Eng., L.R.C.P.Lond., Senior House Surgeon to St. Bartholomew's Hospital.

HEPWORTH, F. A., M.E.C.S.Eng., L.R.C.P.Lond., Junior House Physician to St. Bartholomew's Hospital.

HOGARTH, A. H., M.E.C.S.Eng., L.R.C.P., Assistant Extern Midwifery Assistant at St. Bartholomew's Hospital.

HORDBE, T. J., M.D., B.Sc.Lond., M.R.C.P., Clinical Assistant to the Department for the Diseases of the Skin, St. Bartholomew's Hospital.

MACFADYEN, N., M.R.C.S.Eng., L.R.C.P.Lond., Assistant Extern Midwifery Assistant at St. Bartholomew's Hospital.

MURISON, A. LOGAN, M.R.C.S., L.R.C.P.Lond., Surgeon to the Royal Ear Hospital, Soho, W.

NELIGAN, A. B., M.R.C.S.Eng., L.R.C.P.Lond., Senior House Physician to St. Bartholomew's Hospital.

## Births.

COLEMAN.—On September 28th, the wife of J. G. B. Coleman, M.E.C.S., L.R.C.P., Sutton Bridge, of a daughter.

GOING.—On September 28th, at Erinagh, Littlehampton, the wife of E. M. Going, F.R.C.S.Eng., of a daughter.

PINCHES.—On October 1st, at 20 Margaret Street, Cavendish Square, London, the wife of Major W. H. Pinches, R.A.M.C., of a daughter.

## Marriages.

CUTLER—PHILLIPS.—On September 28th, at St. Albans Abbey, Horace Cutler, M.A., M.B., B.C., of Broughton, Hampshire, fourth son of Samuel Cutler, of West Bank, Lewisham Hill, to Edith Maud, second daughter of Arthur F. Phillips, of Torrington House, St. Albans.

RIDDELL—WILSON.—On September 29th, at St. James's Parish Church, Dover, by the Rev. A. Howell Smith, Rector, Robert George Biddell, M.B., F.R.C.S.E., D.P.H., Rotherham, to Annie, daughter of the late James Wilson, Esq.

## Deaths.

BURMAN.—On October 2nd at 43 Nightingale Road, Clapton, William Minin, eldest son of the late William Burman, surgeon, in his 75th year.

# The Medical Press and Circular.

## Original Communications.

### HOSPITAL ISOLATION AND SCARLET FEVER: THE STATISTICAL ASPECT.

By C. KILLICK MILLARD, M.D., D.Sc.,  
M.O.H., Leicester.

Late Medical Superintendent, City Hospital, Birmingham.

IN my previous article I stated that the all-important question whether fever hospitals really were doing good could only be finally decided by appealing to statistics, and I mentioned two principal methods of applying statistics to this question. The first was to compare the prevalence of the disease *before* and *after* the establishment of a hospital. The second was to compare towns possessing fever hospitals, and treating a large proportion of their cases in hospital, with towns not possessing these institutions, and in which, therefore, all cases of scarlet fever had to be treated at home.

There are, however, other methods which may be, and have been, tried. Thus, the prevalence of the disease can be ascertained for the different wards and subdistricts of a town, and these can then be compared with one another with reference to the proportion of cases removed to hospital. This method has recently been applied by Dr. Boyd to South Shields, and the result published in *Public Health* for August. From this it appears that, speaking generally, those wards in South Shields in which the proportion of cases removed to hospital is high show a somewhat smaller amount of scarlet fever than do those where the proportion removed is lower. On the face of it this certainly appears to be an argument in favour of hospital isolation. As is so often the case with statistics, however, there is an important consideration which may entirely nullify the apparent significance of such a comparison as this. In South Shields, like other towns, there is a single sanitary organisation and a single system of hospital isolation, and the same standard is adopted in deciding which cases shall or shall not be removed to hospital.

The reason why some districts of a town show a larger proportion of removals than others is solely because the *social* condition of the inhabitants varies. In some districts a large proportion of the inhabitants will belong to the lowest stratum of society, living in small tenements in "slummy" surroundings. In such circumstances, a very large proportion of cases will usually go to hospital. Other districts will contain a large proportion of the more prosperous classes living in newer and

larger houses, and with better sanitary surroundings. In these districts a considerable number of parents will prefer to keep their children at home. Therefore, before we can proceed to deduce anything from the fact that the poorer districts of a town, isolating most, have the least scarlet fever, we must be sure that the difference in social condition is not itself the explanation. Now, although it is often assumed that scarlet fever (like typhus fever) naturally tends to prevail most in the "slummy" or poorer parts of the town, it is probable that the idea, so common with the public, that scarlet fever is associated with insanitary surroundings is only one of the many misconceptions in regard to this disease which need to be removed before we can view it in its true perspective. The origin of the belief can readily be traced to the association of ideas in connection with the term "fever." Personally, I am inclined to think that scarlet fever is naturally less prevalent in the more "slummy" parts of a town, and I may say that Dr. Boyd, in the paper referred to above, also lends support to this view. It is important that this point should, if possible, be settled, and the experience of towns where there is no hospital isolation to confuse the issue ought to enable this to be done.

Another method of using statistics to determine the value of hospital isolation, and one which has several times been adopted, is to make a comparison in a given town between the secondary cases which occur in houses where the primary case is left at home with those which occur where the primary case is removed to hospital. We should certainly *expect* that in the latter class there would be a smaller proportion of secondary cases, and this has generally appeared to be the case. *A priori*, indeed, this seemed such a very probable result that until quite recently it was scarcely challenged, and it was looked upon as a strong statistical proof of the value of hospital isolation. But Dr. Niven, of Manchester, who has devoted special attention to this subject, has recently pointed out in his Annual Report for 1903 that there is a very important precaution to be taken, and without it the results of this method are likely to be most misleading. The precaution is this: It frequently happens that cases of scarlet fever occur so slight in character that they are not at first recognised as scarlet fever, and they are therefore allowed to remain at home and no attempt at isolation is made. Such cases may give rise to several other cases in a family, and their real nature is then discovered. These overlooked cases give rise to a very high proportion of secondary cases, and unless they are carefully picked out and

excluded from the group of home-treated cases they will unfairly "weight" that group. Dr. Niven, moreover, is careful to take into consideration "return cases," a certain proportion of which always occur after the return home of the hospital-treated patients.

The following figures are a summary of an important table given on page 97 of the Manchester Health Report for 1903:—

SCARLET FEVER IN MANCHESTER, 1901-1903.  
An Abstract of Dr. Niven's table on page 97 of his Annual Report for 1903.

	Number of Primary Cases.	Number of Susceptible Persons under 15 years Left at Home	Number of Secondary plus Return Cases.	Percentage calculated upon number of Susceptible Persons under 15.
Removed to hospital . . . . .	2,681	5,040	738	14.6
Treated at home . . . . .	573	560	90	16.0
"Overlooked" cases . . . . .	214	431	288	66.8
	3,468	6,031	1,116	38.1

Although Dr. Niven is an advocate of hospital isolation, he is constrained to admit (page 102) that as regards his own figures hospital isolation shows little material saving so far as the other inmates of infected houses are concerned.

There is another method which has been very frequently employed, but which is also liable to be misleading, and this is to compare the relative *fatality* among home-treated and hospital-treated patients. On the face of it, this seems a reasonable enough method, and so long as it was believed that hospitals were accomplishing a great amount of good, no surprise was felt when it was found, as usually proved to be the case in most towns, that the fatality among the hospital-treated patients came out distinctly lower than among those treated at home. In some annual reports calculations were even made, using the relative fatality among hospital and home-treated patients as a basis, to show the actual number of lives which were supposed to have been saved through the superior treatment received in hospital. But, unfortunately for these calculations, the difference in some towns between the hospital-treated and home-treated patients came out so impossibly great that even the most sanguine could scarcely accept them. Thus, in Warrington, for the ten years 1890-99, the home fatality was 19.2 per cent., against a hospital fatality of 7.2; whilst in Huddersfield, during the same period, the figures were 16.9 against 3.2. In the latter town, indeed, in the year 1899, the figures were: hospital cases, 1.5 per cent.; home cases, 28.5 per cent.! It is clearly quite impossible to accept these figures seriously. Among the towns without isolation hospitals, in which, therefore, *all* cases were home-treated, no such abnormal fatalities are anywhere to be found. Indeed, the fatality of scarlet fever in the non-isolating towns is, speaking generally, in no degree higher than in the isolating towns. The explanation of the apparently terrible fatality in the home-treated patients in Warrington and Huddersfield is simply this: in these towns the home-treated group is a small one, most of the cases going to hospital. A few cases, however, are too ill to be removed, and are left at home to

die, and these unduly "weight" the home group. In other words, a certain amount of *selection* must inevitably take place of the cases that go to hospital and of those that remain at home, and this completely invalidates a comparison between them. Now, the same causes which have operated in Warrington and Huddersfield may be presumed to have operated, though to a less extent, in other towns, and unless we can positively exclude them, which is scarcely possible, it must obviously be most unsafe to trust to any comparison of this kind.

Moreover, there are some towns, *e.g.*, London and Birmingham, where the fatality of the hospital patients is actually higher than that of those treated at home. This also is explainable by the selection of cases which takes place, hospital patients being drawn from a different social class. There are few, I think, who would care to contend that the higher fatality of the hospital patients in London is any evidence of inferior treatment; but if the comparison is not admitted in the case of London, or wherever it tells against hospital treatment, ought we in fairness to make use of it just when it happens to tell in favour of such treatment?

Before leaving the subject, I would take exception to the contention sometimes put forward that those who have criticised the hospital isolation of scarlet fever have not yet conclusively *proved* that it is doing no good. Surely, the burden of proof in such a case as this should be with those who advocate hospital isolation rather than with those who criticise the measure. On the one hand we have men who, in spite of much admitted evidence of a most discouraging nature, still continue to advocate the building of further hospitals on the old lines, just as if they were accomplishing all that was originally expected of them. On the other hand are those who merely advocate that the whole question should be thoroughly investigated before further increasing the already large capital expenditure on hospitals.

Then, again, it has frequently been urged that those who have criticised hospital isolation have nothing better to offer in its place. Surely, this is not a valid objection. A precisely similar "objection" could have been urged against those who first criticised blood-letting or any other now obsolete but once much-vaunted measure! If a thing is doing no good, or, at least, yielding no results commensurate with the cost entailed, no substitute for it is required.

I think I have said sufficient to show that the question of the utility of fever hospitals is a highly complex one, and that many of the arguments put forward in support of it require careful examination before they can be accepted as conclusive. The same, no doubt, applies to some, at least, of the arguments used against it. The present state of affairs is eminently unsatisfactory. If it were a subject of dry scientific interest, only it would not so much matter, but unfortunately, the questions at issue are involving a large and increasing expenditure of public money which is very badly needed for many other public health purposes. As the late Sir John Simon wrote, nearly forty-five years ago, in one of his classic reports to the Privy Council, when attacking the evils of overcrowding in general hospitals: "The doings of hospitals and the relative successfulness of such doings are of great public importance; and all

questions concerning them ought to admit of being answered quite unambiguously to the public."

## INFLUENCE OF NUCLEIN IN THE TREATMENT OF BRIGHT'S DISEASE OF THE KIDNEYS AT A HIGH ALTITUDE.

By A. S. ASHMEAD, M.D.

IN a case of chronic Bright's disease treated by me in the Pocono Mountains, the camp for the treatment of consumption, Pike County, Pa., at an elevation of 2,000 feet, I record the following results:—The urine at once became very red, and continued so for two weeks. This was probably due to increase of uro-hæmatin, by the influence of the particular remedy used and the peculiarity of ozonised air of the region and its influence on the liver and blood.

An increase of drinking water or other liquid is necessary at this height, more than is required at lower elevations, where the air is less dry; and, in consequence, there is increased urination.

Meat as an article of diet is not craved here, but starches, especially potatoes, are consumed with the greatest avidity. Even a moderate supply of meat, say, once a week, proves to be too much for the system. Old residents are not quick of bodily movement—they walk slowly, work leisurely, and seem to act in everything they do in a lazy manner. This is not because they are really lazy; the peculiarity is not temperamental by any means, but it is because the air here does not permit of alacrity.

One soon adapts one's self to this variation of life's conditions, and lazy actions soon take full possession of even the alert New Yorker. This laziness is most natural; one's muscles soon tire out; sleep is the order of the day, rather than merely of the night, and especially does the feeling of drowsiness overcome one for two hours after rising. The ozonised air, the dry mountain breeze blowing all the time gently stimulates the circulation of blood in the brain's arterioles, while at the same time there is increased fulness of the veins.

Insomnia could not exist here. Nutrition is influenced naturally and quickly by the sole influence of the air, and independently of the food taken in. Tissues are thus to a great extent nourished by air rather than by food, and oxygen is required instead of meat.

Hæmatin, the colouring matter of the red blood cells, is formed in greater proportion than necessary, and an increased supply of drink is demanded to wash from the blood the over-supply. Thus matters are equalised.

Nuclein, in 10-drop doses, in diseases of the kidneys seems to help the establishment of this equilibrium. It is the only remedy, in my opinion, that will do this. Hæmatin by itself in Bright's disease is perhaps curative, but the effect of the altitude and ozonised air in producing it in greater quantity does not seem to me to last sufficiently long to effect much result, for in two weeks the urine has become of natural colour.

Even advanced cases of this disease will find immediate relief by the conjoined treatment of nuclein and altitudinal air. The diuretic effect of life at an altitude and by breathing the percentage of ozone that exists here is not due alto-

gether to the nuclein. The hæmatin itself has an influence on the albumen, even when formed in normal amount, and an increased elimination of poisonous urea results. The chief plastic element of human blood is albumen. Œdematous effusions in Bright's disease follow elimination of albumen. Any oxidising agent, astrontia salt, sulphuric or nitric acid, will produce precipitation of albumen, and ozonised air will do the same thing.

Carbonic acid, as we all know, acts as a natural stimulant to the heart or arterial system, but ozonised air, its absolute opponent, has the contrary effect, for the veins, as well as arteries, are filled to overflowing by highly-coloured blood. Nuclein, therefore, is a necessary element to add to the natural treatment for its desired effect on leucocytes. Better equalisation of the component parts of all secretions is the result of the combined treatment of altitudinal air and nuclein.

The liver is the great assimilating organ of the human economy. Albuminose, which is carried through it in its passage, is brought into contact with the hepatic cells and converted into albumen. Albuminose is never found in the hepatic vein, the exit from the liver, therefore this substance is (or should be) all converted into albumen.

In a climate like this, where so little albuminous material is required, where one craves none at all almost, a disease like Bright's disease which produces, independently of the food, more albumen than the blood takes up must necessarily cure itself if only helped by a drug which will equalise the composition of the blood. The poison of Bright's disease is urea, to be sure, a 50 per cent. nitrogenised material which is retained in the blood instead of being washed out naturally; 500 grains a day should be eliminated, or thereabouts. If too much of it is retained in the blood, we have convulsions or coma.

This substance comes naturally from the disintegration of the tissues and following much exercise; the broken-down muscular tissues form a great quantity of it. Thus in Japan a jinriksha man, after a long run with his passenger, will show in his urine a superabundance of this excrementitious substance. In this altitudinal climate the cold air blowing constantly produces an indisposition to take much physical exercise; the muscles are always lazy, so that there is induced the condition directly antagonistic to the formation of urea in the blood, and the disabled kidney is not required to excrete an excess of the material. It is given time to resuscitate itself. There is a quick betterment, not only by reconstitution of the albumen-forming process of the economy by ozone (red corpuscular element) and nuclein (white corpuscular element), but there is no increased burden to be borne by it, put upon it to eliminate the excess of urea, and the dangers of uræmia are thus averted, while the albuminuria disappears, and the amount of urine increases and washes clean and heals the diseased organ.

### Typhoid in New York.

THE Health Department of New York fears that a serious epidemic of typhoid fever is developing in the city. During the past three weeks 441 cases have been reported to the city authorities, of which seventy-four have resulted fatally. The Health Department believes there will be an increase in the number of cases during October and November, and has issued a public warning against the consumption of oysters and of unboiled milk and water.

## THE DRINKING HABITS OF UNCIVILISED AND SEMI- CIVILISED RACES. (a)

By CHAS. FORBES HARFORD, M.A. Cantab., M.D.,  
Principal of Livingstone College.

THE protection of the weaker races of the world from demoralisation by the liquor traffic has for many years past occupied the attention of a special committee, the Native Races and the Liquor Traffic United Committee. In the course of these investigations, which have been chiefly directed towards the obtaining of legislative reform, some valuable facts have been recorded concerning the drinking habits of these races which are of the greatest importance. Naturally, these habits differ in each country, often in each district, so that instances can only be quoted as examples from the most important centres, though there are certain points of general resemblance to which attention may be directed. Perhaps the most convenient method of considering this subject will be to classify the different kinds of drinks which are commonly used, noting, where possible, the way in which they are used, and the effects which they produce. They are as follows:—(1) *Non-Alcoholic Beverages*.—Water, milk, palm wine and cocoanut milk when fresh, tea and coffee, drinks made with various kinds of meal and water. (2) *Native Fermented Drinks*.—Various forms of corn beer of varying alcoholic strength, palm wine, cocoanut milk and the like which have been allowed to ferment. (3) *Distilled Liquors*.—Native spirits (especially such as are prepared in India), Cape brandy, potato spirit, prepared especially in Germany for consumption in West Africa. These classes of liquor may be taken as samples of the drinks used by the native races, especially of India and Africa, the wines, beers, and the better forms of spirits manufactured in England and other European countries being almost left out of account as they are in the main too costly for wide use. (1) *Non-alcoholic Beverages*.—Chiefly used by the races concerned with their meals, but as we are dealing mainly with the liquors which produce intoxication little need be said about them. (2) *Native Fermented Drinks*.—Palm wine and similar products do not usually contain a large percentage of alcohol, but when large quantities are taken intoxication may be produced. Sir William Macgregor estimates the strongest form of palm wine to contain less than 3 per cent. of alcohol. There are many varieties of corn beer. Mr. Joseph Orpen, of Rhodesia, has given some valuable information about different kinds of what are known as Kafir beer; one form, "leting," he describes as an acid refreshing drink of little or no intoxicating quality. "Joala," on the other hand, which is more properly known as Kafir beer, is generally made with the object of producing drink of the greatest intoxicating strength attainable by native manufacture. It is used purposely to produce its toxic effects, and is drunk in large quantities till the stomach is quite distended. It has a stupefying effect, and, in addition, produces violent headaches and indigestion, even when not mixed with spirits, which is often done. Probably drugs such as bhang are frequently added to these native drinks for purposes of intoxication, and this accounts for much of the evil produced by them. (3) *Distilled Liquors*.—Mr. H. H. Mann, M.Sc., has furnished some valuable particulars as to native spirits manufactured in India. Some of those prepared in Assam, for instance, are particularly injurious, containing large quantities of fusel oil and other specially poisonous ingredients, in some cases about twenty times as much as would be found in a properly matured Scotch whisky. This he attributes to want of supervision by the Government and the fact that the spirit is not allowed to mature. As regards the

results of the drinking of such spirits, the case of Assam may again be quoted. So serious has the situation become in that province that the Assam branch of the Indian Tea Association, represented by their chairman, Mr. Buckingham, C.I.E., have recently petitioned the Government to amend the law relating to the sale of liquor in that part on account of the serious effect produced on their native labourers, a striking evidence of the gravity of the evils complained of, and the Government are taking steps to remedy some of the abuses. Similar complaints have been frequently made by employers of labour in South Africa, and have resulted in the stringent laws prohibiting the sale of liquor to natives which have existed for some time in the territory administered by the British South Africa Company, a policy which was strongly approved of by Mr. Rhodes, which was secured for Bechuanaland by the splendid persistence of Khama, and which has been introduced in a rigorous manner into the Transvaal and Orange River Colony by Lord Milner. This latter, whilst prohibiting the use of spirits and the stronger forms of Kafir beer, permits, under certain conditions, the supply of the milder forms containing not more than 3 per cent. of alcohol. This beneficial legislation has not been extended to Cape Colony, where a pernicious form of brandy is made from grapes known as "Cape smoke." Samples of this are said to have been found to contain copper sulphate, and it appears to be particularly intended for native consumption, it might also be said for their degradation, and this produces untold harm. Unfortunately the strong views entertained by practical men in South Africa has not extended to West Africa, where immense quantities of potato spirit, manufactured in Germany for the purpose, form the largest part of the trade of Great Britain, as well as of France and Germany, with the West African natives. This spirit is frequently shipped in a concentrated form containing about 80 per cent. of alcohol, and some samples of this were found to contain as much as 4 per cent. of fusel oil. Trade gin and rum, as they are called, can have but one use, *viz.*, the intoxication of the native. No respectable European will ever touch them, and they have been known to have been used for mixing with paint instead of turpentine. They are used principally on the occasion of funerals and at festivals. It is contended that there is not so much drunkenness in West Africa as in England. There is an element of truth in this, and we can only hope that it may never become so. But the facts of the case are probably as follows:—(1) The West Africans are naturally a sober people and they do not want the drink, but are too weak to resist it if taste for drink has been deliberately encouraged by the traders of a so-called Christian country, and maintained for the sake of profit, whilst the local Governments do little to stop it on account of the revenue. (2) Drunkenness is not so easily noticed among the Africans, as they drink at home and not at public bars, so they are able to sleep off the effects before coming before the public. On the occasion of festivals, however, drunkenness is sometimes very widespread. Thus it will be seen that most of the weaker races are not naturally drunken, and the responsibility lies with professedly Christian nations. In the case of these races, especially in Central Africa, the outlook is most hopeful, as it is in dealing with children at home, in that prevention may be adopted, which in this, as in so many other cases, is infinitely better than cure. This should be our aim.

### Requests to Medical Charities.

UNDER the will of John Earley Cook, of Cobham, Surrey, who died in February last, the London Hospital receives a legacy of £2,000; St. Bartholomew's Hospital, £1,500; the Metropolitan Convalescent Institution, £1,000; Earlswood Asylum, £500; and £200 to the Margate Infirmary and to the Seaford Convalescent Home.

(a) Paper read at the meeting of the Society for the Study of nebrity, October 11th, 1904.

# THE HEADACHE OF ANÆMIA AND ITS TREATMENT.

By DAVID WALSH, M.D. Edin.,

Senior Physician to the Western Skin Hospital, London.

HEADACHE is of necessity a common occurrence, for it is a prominent symptom of nearly all the acute specific and of many chronic ailments. Sooner or later its far-reaching importance as a symptom is brought home to every physician, for there is no class of malady in which the teachings of the class-room and of the text-books need to be more carefully controlled by actual bedside experience. In some cases it is what, for want of a better term, we call "functional," whilst in others it points to grave organic disease. We have always to be on the alert for the obscurer and more serious forms, for they constitute an ever-present pit-fall of practice.

Headache is due to some disturbance of the nutrition of the brain, brought about by circumstances that differ widely in different cases. Speaking generally, it connotes either alteration in the condition of the blood or interference with its circulation in the higher centres. It varies not only in its severity and intensity, but in its situation and in the duration of the paroxysms. It may be sudden, sharp and excruciating, or it may be dull, aching and persistent. It may be so intense as to unfit the patient for work, or it may be so mild as to be felt only after exertion. Nervous headache, the result of anæmia, not infrequently affects the sufferer at intervals throughout a long life. It is the accompaniment and curse of high intellectual endowment, and is most marked when the functional activity of the brain, whether in perception, emotion, or intellect, outstrips the vigour of the rest of the body.

Headache is often associated with other symptoms, such as dizziness or vertigo, a general sense of pressure or discomfort in the head, a disturbance of cerebral function with insomnia and with attacks of nausea or vomiting. It is not the purpose of this article to consider exhaustively the entire subject of headaches, but merely to discuss that form associated with anæmia, especially in reference to the symptomatology and treatment of the same.

Reflex headaches need not be more than mentioned here, as in the individual case a correct diagnosis indicates the proper line of treatment. An example of purely reflex headache is that due to eye-strain. Many so-called reflex headaches in reality arise from other causes. In ulcer of the stomach and in constipation, for instance, headache is probably due most often in the one case to the accompanying anæmia, and in the other to toxic absorption from the bowel.

Headache is a common symptom of dyspepsia and is usually of a dull, aching character, involving both frontal and vertical regions. Depression and irritability are often quite out of proportion to the amount of gastritis and may end in neurasthenia. There is often constipation alternating with diarrhoea, a condition toxæmic in character and allied to copræmia. It often happens that even when the bowels have been relieved and the gastric irritability lessened the headache still keeps the patient awake at night. Such cases are not uncommon in middle-aged men of great mental activity, whose nervous system has been run down by anxiety and mental strain. It is found in these individuals that the hæmoglobin is subnormal and that the red cells are not only diminished in number but are small, irregular in shape, deficient in colour, and immature. The judicious administration of iron in a non-astringent and readily assimilable form usually effects a cure. With the restoration of the blood cells and the hæmoglobin value to the normal, the headache speedily ceases, the appetite improves, the irritability of temper is lessened, and there is an increase of energy and capacity for work.

That impoverishment of blood is an important element in many cases of migraine or sick headache, and that treatment directed to improving the con-

dition of the blood is the proper step, are points illustrated by the following cases:—

CASE I.—M. B., a woman, æt. 30, had suffered from migraine for over ten years, the attacks coinciding with the occurrence of the menstrual periods. She had had much treatment, including arsenic, gelsemin, butyl-chloral hydrate, and various courses of Bland's pill, but without benefit apparently. She was not anæmic in appearance, but on examination the red blood corpuscles were found to number only 3,600,000 per c.mm., the hæmoglobin estimate being 46 per cent. She was given iron-vitellin, and in ten days her red cells rose to 4,700,000, and the hæmoglobin to 66 per cent. There has been no recurrence of the migraine, and the patient is now apparently perfectly well and has had no attack for three months. Many cases of migraine or sick headache are associated with anæmia. The attacks are of a paroxysmal or intermittent character, the seizures usually incapacitating the patient for three or four days at a time.

CASE II.—A governess, æt. about 26, suffered from periodical attacks of migraine or sick headache, induced by excessive brain-work, over-anxiety, and long hours, combined with deficiency of bodily exercise, short restless nights and disturbed sleep. The seizures were paroxysmal or intermittent in character, and occurred usually every three or four weeks, incapacitating the patient one to three days at a time. The headache was severe and was accompanied by loss of appetite, nausea and vomiting. The patient suffered from dysmenorrhœa, and the attacks usually preceded the onset of the menstrual period. It was noticed that the susceptibility to the migrainous attacks was aggravated by anything tending to lower the general standard of health, such as dyspepsia or constipation. The patient had had much treatment extending over a long period of years, the remedies prescribed, with little or no benefit, including arsenic, phosphorus, Bland's pill, gelsemin, butyl-chloral hydrate, phenacetin, &c. The patient presented no very obvious signs of anæmia, but a blood examination showed that the red cells were only 2,500,000 per c.mm., the hæmoglobin being 36 per cent. It was found impossible to improve her hygienic condition or obtain for her a cessation of work. She was given iron-vitellin three times a day for three weeks, and at the expiration of that time the red cells had increased to 4,600,000 and the hæmoglobin to 61 per cent. Her general condition was markedly improved, her appetite was increased, the periods were less profuse, and for three months the attacks of migraine have been so slight as not to incapacitate the patient for a single day.

The commonest form of headache met with in practice is that in which the subjective and objective symptoms of anæmia are striking and easily recognisable. In these cases the headache is usually vertical as regards situation, although it may now and then be frontal. It is due to the fact that the brain is supplied with blood which is deficient in quantity and poor in quality. Patients suffering from it are often drowsy in the upright position but wakeful in bed because the blood fails to distend the cerebral arteries during the day but flows into them at night. In some cases not only is the blood poor in quality, but it also contains abnormal and toxic constituents. The result is a condition of arterial spasm which may give rise to sudden loss of consciousness. It is the converse of the plethoric headache met with in elderly men who are free livers with regard to food and alcohol, and who from want of sufficient exercise suffer from constipation and deficient urinary secretion. The subjects of chlorotic headache are usually young women, although the condition is by no means uncommon in middle-aged spinsters. That iron is the most efficient remedy in these cases is illustrated by the following notes selected from a series of similar cases which have been treated in exactly the same manner.

CASE III.—A married woman, æt. 24, suckled her first child for six months, and for two months subsequently suffered from paroxysmal headache, the pain being situated over the brows and in the eye-balls,

which, she said, seemed too large for the head and as if they would be forced out of the skull. There was tachycardia, but there was no actual prominence of the eye-balls and the thyroid was not enlarged. The patient presented the ordinary signs of anæmia with palpitation and shortness of breath on exertion. The red blood corpuscles numbered 2,560,000 per c.mm., and the hæmoglobin value was 34 per cent. The patient was given iron-vitellin three times a day, and four days later the red cells were 2,750,000, the hæmoglobin value being 38 per cent. A week later the red cells had risen to 3,400,000, and the hæmoglobin value was 42 per cent. At the expiration of twenty-one days from the commencement of treatment the red cells were 4,200,000, and the hæmoglobin value was 82 per cent. The headache rapidly improved and at the expiration of the three weeks' course of treatment had entirely disappeared. The typical consulting-room case of the character just recorded is that of a young woman of white or greenish tint, who complains of weakness, constipation, and amenorrhœa. An examination of the blood reveals a marked diminution of the red corpuscles together with a deficiency of hæmoglobin, perhaps to the extent of 50 per cent. or more.

The two following cases illustrate headache due to anæmia arising from different causes:—

CASE IV.—A married woman, æt. 36, the mother of four children, after enjoying many years of uninterrupted good health, suffered from a profuse vaginal discharge followed by chronic arthritis, possibly gonorrhœal in origin. Under the influence of salicylate of sodium the joint trouble subsided, but was replaced by brachial neuralgia and frontal headache, worse at night and of so severe a character as to interfere with rest. Iodides in large doses were tried in vain, and other remedies, such as aconitine and gelsemin, afforded but temporary relief. The patient was distinctly anæmic, the tongue was large and flabby, and there was little or no appetite. A month spent at a bracing seaside resort, although it improved the patient's general condition, failed to relieve the neuralgic pains in the arm and aggravated the cephalalgia. Iron-vitellin in half-ounce doses was then ordered, at first without apparent benefit, but after six weeks' treatment the symptoms gradually subsided, and the patient made an excellent recovery, the leucorrhœa giving no further trouble.

CASE V.—A man, æt. 48, who had had many attacks of malarial fever in India, and for many years had indulged freely in alcohol, sought advice for persistent headache of a throbbing character. He showed signs of advanced arterial degeneration and was evidently suffering from granular contracted kidney. The urine had a specific gravity of 1007, contained a fair amount of albumin with a few coarse granular casts. The patient was dieted, his nitrogenous food being reduced to the minimum, and he was given directions with respect to the general care of his health and systematic exercise. His condition improved, but the headache was persistent and was a source of considerable discomfort. The patient was then placed on iron-vitellin, and at the expiration of a week there was a distinct lessening of pain. After a month the headache ceased, there being concurrently an improvement in the condition of the urine, although a trace of albumin remained.

So far as the treatment of anæmia is concerned, apart from measures such as pure air, liberal diet, good surroundings, and regulation of the bodily functions, hæmatinics are the only remedies that need be discussed. They are not medicines, but foods. There are many reputed hæmatinics, but iron is the only member of the group which is practically efficacious. Phosphate of lime, arsenic and manganese are of little or no avail in this connection, and are not true hæmatinics. Under the influence of iron in anæmia the cheeks grow rosy, the lips and mucous membranes are restored to their normal character, the eye brightens, the tongue cleans, the digestive organs are invigorated, there is an increase in body weight, a development of muscle and improved nerve action. The modern tendency is to discredit arsenic and manganese more and more in the treatment of anæmia. Physicians agree that success depends to no small extent upon the particular preparation of iron

that is used. That fact has been abundantly proved by experience with the old-established and classical remedies for anæmia, namely, the tinctura ferri perchloridi, the sulphate of iron, Blaud's pill, and the aloes and iron pill of the British Pharmacopœia. These astringent preparations of iron are placed at an immediate disadvantage by the fact of the close association of constipation with anæmia. Clearly, it is undesirable to administer drugs that have an astringent or constipating effect, even though such an effect may be to some extent reduced by combining the astringent iron with a laxative, as in the familiar *mistura ferri aperiens* of hospital practice. But whatever the uncertainty that surrounds the chemical changes undergone in the passage of inorganic iron from the intestine to the blood, there can, on the other hand, be no question as to the ill effects produced by astringency upon the digestive, the absorptive, and the expulsive functions of the gastro-intestinal canal.

Taking the chief preparations of inorganic iron one by one, we find that Blaud's pill often increases constipation and headache. The tinctura ferri perchloridi does the same, and in many cases irritates the delicate mucous membrane of the stomach, probably by coagulating the albumen of the gastric contents and of the mucous lining cells, besides constricting the capillaries of the stomach wall. It has always seemed to me that not a few ulcers of the stomach in anæmic women may have been caused by the prolonged action of astringent iron remedies to which they have been subjected. Otherwise, why should a patient actually develop gastric ulcer during a long-continued course of iron? Instances of that kind are familiar enough in hospital practice. If astringent iron upsets a healthy stomach, as it often does, it is likely to act far more injuriously upon a weak, anæmic organ. The objection of astringency applies also to the sulphate of iron, whether given in the form of mixture or of pill. In Blaud's pill, the iron is comparatively non-astringent, but its administration is often most disappointing, and it certainly increases constipation and headache in some cases. The old-fashioned aloes and iron pill is undoubtedly effective in many cases of amenorrhœa. As a temporary remedy, it is often of value, especially in full doses of ten or fifteen grains daily. I have known a patient, however, keep on with these pills for nearly two years, to the great detriment of her health. Lastly, a good deal of harm may result from setting up a chronic congestion of the female pelvic organs.

Organic iron approaches more or less closely the form in which iron is absorbed from ordinary food. From that point of view the administration of egg-albumen or of spinach, or of other iron-containing foodstuffs, would alone suffice to cure anæmia. Experience, however, has long shown that for some obscure reason it is necessary to give iron preparations in doses far exceeding the capacity of intestinal absorption.

The difficulty so far has been to obtain a true organic salt of iron, but the problem appears to have been solved in the production of iron-vitellin, a tasteless and non-astringent preparation, which increases the appetite and possesses well-marked hæmatinic properties. It improves in a remarkable degree the condition of the blood, increases the red cells at the rate of 100,000 a day or more and the hæmatinic value from 1½ to 2 per cent., a result far in excess of that resulting from the administration of any form of inorganic iron. Its chief clinical advantage, however, is that it has a general stimulating influence upon the processes of nutrition, thereby exerting a tonic and reconstructive action which I have never observed from the use of any other form of iron.

In conclusion, the point I desire to emphasise is this: Anæmia is the causative condition of many of the most frequently encountered cases of headache, although in many instances the impoverishment of the blood may not be apparent from the general appearance of the patient. Blood examination, however, and a careful analysis of the symptoms, will reveal marked deficiency in the percentage of the hæmoglobin or red blood corpuscles, and one or more subjective symptoms of anæmia. So frequently is this the case that it is

well to examine each patient with headache from that standpoint and to begin the administration of iron, preferably in the form of iron-vitellin, along with the preliminary hygienic and dietetic measures. This has been my practice for some time past and I have had every reason to be satisfied with its results.

## Special Articles.

### LUNACY IN IRELAND.

THE Annual Report of the Richmond District Asylum, Dublin, which has recently appeared, is in every respect an interesting document, and in view of the serious increase of lunacy in Ireland is one that deserves careful study by all interested in the future of the country. If it were only on account of the personality of the Medical Superintendent, who, no matter what his subject, always attracts and retains the attention of his readers, the Report would be of value. In the present instance, however, the facts themselves are of primary importance, though they gain much as food for study by Dr. Conolly Norman's setting and by the addition of his opinions based on them. The increase of lunacy in Ireland, which is causing grave and well-founded alarm at the present day, is unfortunately shown by the steady increase in the number of patients in the Richmond Asylum and its branch at Portrane. During last year there was an increase of one hundred and thirty-nine cases. At the same time it is pleasing to find that the number of admissions during 1903 does not show any advance on that during 1902—the figures being respectively 658 and 662. The number for 1902 was, however, higher by 142 than the highest figure ever reached previously. As in recent years, the cases admitted were mostly of a very unfavourable nature as regards prospect of recovery, many of the patients being in broken health physically, and afflicted with incurable types of mental disease. Suicidal tendencies were more marked than usual, and some interesting cases occurred in which persons with suicidal impulses presented themselves for admission as voluntary patients. Under such circumstances we congratulate Dr. Norman and his staff on the fact that no case of suicide occurred during the year. A freer mode of treating the depressed is practised in the Richmond Asylum than is thought permissible in most other institutions, and it speaks well for the intelligence and tact of the subordinate staff that it is so successful. We are pleased, too, to note that it has not been necessary to resort to restraint on any occasion during the year. Dr. Norman holds very similar views to Dr. Clouston on the importance of alcoholism as a cause of insanity. Of 394 cases for which one probable cause of the condition is assigned, in 127 it is drink. On the other hand, sexual intemperance, which is given a preponderant place in many causal tables, is not here assigned as the cause of a single admission. Hereditary influences are made accountable in 82 cases, but we fancy a much higher figure would have resulted if an accurate family history were in every case available, and if other stigmata were taken into account beside actual previous insanity in the family. The mortality in the asylum during the year is not unduly high—7.9 per cent. on the average number of patients,

but some of the causes seem capable of diminution. Phthisis, especially, is responsible for a greater proportion of the deaths than seems necessary if modern preventive and therapeutic measures are practised, though it must be remembered that it is a disease which in an insane person is very likely to advance far before suspicion is roused. Dysentery also still claims its share of deaths, and typhoid fever, though almost unrepresented in the mortality list, is present in the female house every year. It is interesting to note the variety and number of the industrial occupations in which it has been found possible to engage the great majority of the patients. All the clothes worn in the asylum have not only been made on the premises, but the stuff itself has there been woven. One can hardly think of any occupation from chimney-sweeping to "drawn-thread work," from blacksmith's work to embroidery, at which some of the patients are not employed. The importance of this steady industrial spirit is, from the point of view of economy, great, but far greater when one regards it as a rational, satisfying, and successful method of treatment.

### THE CENTRAL MIDWIVES' BOARD.

THAT curious body—the Central Midwives' Board as at present constituted—met again after an interval of quietude on the 29th ult. There were in attendance a Chairman (Mr. E. P. Young), two ladies (Miss Wilson and Miss Oldham), and a medical man (Dr. Sinclair). The meeting commenced with a discussion on a letter from a medical practitioner. This gentleman wrote to complain of the conduct of a registered midwife, to whom he had written that it had come to his knowledge that she was interfering with his treatment of a child under his care, and that if she continued to do so he would take legal action. The midwife had replied, "You may take legal proceedings whenever you like. It is much like your 'impotence' to write to me, so please mind your own business." This poor woman, who is perhaps only imbued a little too strongly with the spirit of the Board which governs her, is to have her conduct inquired into by the local authorities before the C.M.B. will interfere. We are sure that an excuse will be found for her; after all, imitation is the sincerest flattery. The next business was the reading of a letter from the London Obstetrical Society, informing the Board that the certificate of the Society had been removed from a certain midwife. The C.M.B. decided that evidence should be demanded in support of the charges against the midwife. The Board was next asked to become an architect and to give its valuable opinion regarding the suitability of lying-in wards at Brentford. This it decided to be by the vote of two ladies to one medical man. The Board then discussed the question of the compensation of midwives who were suspended to prevent them from infecting their patients. It was suggested that the Board should promote legislation to such an end, and it was decided that a note should be made of the necessity for so doing, again by the vote of two ladies to one medical man. Dr. Sinclair next asked that the statement of accounts should be sent to the members of the Board a week before the meeting, in order that members might have an opportunity of becoming acquainted with them. At this, the ladies became nervous, and thought that at the discussion of such an important question the presence of Mr. Heywood Johnstone was essential, and must be awaited. After an apparently lengthy discussion, it was, however, ruled by the Chairman that the suggestion made by Dr. Sinclair was unnecessary, and that the present system of springing the accounts on the meeting was sufficient. Accordingly, Mr. Johnstone's presence was dispensed with, and the Board adjourned until October 11th.

## THE EXAMINATION OF WATERS. (a)

Books on this subject are, perhaps owing to the limited demand, not very numerous, and, with few exceptions, those that are in use are out of date, owing to the rapid advance of knowledge in this direction; consequently, a book written by Dr. Thresh, who has acquired a reputation in the subject of water supply in its manifold bearings, is sure of a welcome. It is nothing new to medical officers of health, and to analysts, to be told that an examination of the source of supply of a water often affords more important information than could be obtained from analytical or bacteriological examinations, as these only show the condition of the water at the time the sample was taken, while an examination of the immediate neighbourhood of the source of supply may, and usually does, show the chances of possible pollution. In his preface the author says: "In numerous instances I have had to investigate supplies which have been the cause of outbreaks of disease, and in many others to investigate the cause of some change rendering the water objectionable in character. In nearly all such cases I have found that the examination of the source of the water afforded information without which the chemical, bacteriological, or microscopical examination of the water could not have been correctly interpreted." We think that this must be a slight exaggeration; coming as it does from one who has had much experience in the analysis of water, while the many and varied instances given in the book of the value of analysis seem to contradict this. On the contrary, Dr. Thresh seems to have shown more conclusively than we have seen elsewhere that the chemical, bacteriological, and microscopical examination of a water is usually sufficient to condemn it or even to pass it, when the few details asked for by the analyst as to the depth and nature of the well are answered, though, as we have previously remarked, possibilities of pollution are sometimes revealed by an examination of the source of supply. Our experience is similar to Dr. Thresh's in the discovery of sources of pollution by microscopical examination, which had been overlooked at a careful inspection. All persons acquainted with the subject will also agree that "much more skill and care (in the analysis of water) are requisite to obtain concordant and accurate results than is generally imagined."

"The chief object of the work, however, is to show how to examine sources of supply, and how to use the information thus acquired, in the interpretation of results obtained from the examination of the waters yielded by these sources, and to demonstrate that it is more important to consider the quality than the quantity of the organic and inorganic constituents found in waters from whatever source derived." The condemnation of standards is the view adopted by all who have had any experience in the analysis of water. Dr. Thresh remarks, "Standards may be useful to the beginner and the inexperienced," the logical sequence being that only those falling in this category—we have all been included in it at some time or other—patronise standards.

His book is divided into three parts:—(1) The Examination of the Sources from which the Water is Derived; (2) Various Methods of Examining Water and the Interpretation of the Results; (3) Analytical Processes and Methods of Examination. In reading the first of these parts, in which the author is at his best, one cannot help admiring the excellent way in which the subject is handled. It is well written, illustrated with numerous and aptly chosen instances of the cases in point, and forms interesting as well as instructive reading. The examination of shallow and deep wells, springs, surface water supplies, rivers and streams, service reservoirs, water mains, &c., is well described; and though much

of the information is not new to those acquainted with the subject, yet it is necessarily included to ensure a better appreciation of the many details that will be new to not a few readers.

In the second part Dr. Thresh is touching a delicate subject and adding fresh fuel to the controversy which, for the sake of the professions interested, we are glad to see going on. There is probably no one so without bias that he looks on the question of the relative values of bacteriological and chemical analyses with an impartial eye. Some lean one way, some the other. The more bigoted do more than lean—they boldly declare that there can be no possible advantage in performing a bacteriological or chemical analysis, as the case may be; in fact, to do so is likely, if not certain, to be misleading. In most cases this is due to lack of experience of the processes they so freely condemn. We have here a book written by one who, from his experience in both chemical and bacteriological methods, ought not to be biased, but Dr. Thresh is human—his book reveals it—and although he nearly takes the *via media* (proverbially the safest), he has a slight, but still an apparent, leaning towards the bacteriological side of the controversy. Nevertheless, he is very fair. "There is now a general opinion that a bacteriological examination is more important than a chemical analysis. This is undoubtedly true in some cases, but not in all. . . . When we find that waters used for long periods by large communities are condemned by bacteriologists as being dangerously polluted, and that the results obtained from the same water by different bacteriologists differ to an extent which is impossible in a chemical analysis, our faith in bacteriological examination is somewhat shaken." And again: "It is obvious, therefore, that chemical and bacteriological examinations have their special uses, and that one can rarely replace the other," but (p. 133) "bacteriology can tell us but little, if anything, of such past pollution."

Dr. Thresh lays much stress on the colour of a water. "The medical officer of health or sanitary inspector making inspections of districts supplied with water from shallow wells or similar sources of supply may be guided in their selections of samples for analysis by viewing some of the water in a deep tumbler placed on a sheet of white paper. Those in which a yellow tint is observed are the most likely to be impure." Though this in many cases, perhaps in most, may be true, it is misleading, inasmuch as it seems to suggest that absence of yellow colouring (in such a short vessel as a glass) would render it very probable that the water was pure. We should hesitate very much to say that this very slender piece of evidence was sufficient to justify neglecting to have the sample examined. Surely, if the expense of having all the samples fully analysed was prohibitive, it would be better for the M. O. H. to do as he is elsewhere urged—examine the source, and if that did not afford sufficient grounds for rejecting the water, partial analysis might be contracted for, or even the cheap process described in "A Simple Method of Water Analysis" would be better than trusting to the colour.

A readable chapter is the "Interpretation of Results of Chemical Examination," in which several matters are mentioned which will be news to many, such as the assurance that there is no vestige of proof in the hakeneyed instance of the increased prevalence of rickets in Glasgow being due to the use of the proverbially soft Loch Katrine water. Dr. Thresh has ceased to determine the hardness of water to less than half a degree, since, as he says, the same examiner sometimes gets slightly different results on the same water, even when using the same solutions. While scoring standards, as we all do, Dr. Thresh wisely gives figures suggesting what amount of the different constituents of water would indicate or suggest sewage pollution, but he seems to allow rather more latitude than most analysts.

We regret we cannot support Dr. Thresh in his statement that "practically all the information

(a) "The Examination of Water and Water Supplies." By John C. Thresh, D.Sc.Lond., M.D.Vic., D.P.H.Camb. Pp. 460, and xvii, 10 plates, 11 illustrations in text and 20 tables. 14s. net. London: J. and A. Churchill, 1904.

necessary may be obtained by an analysis made as described by me in a pamphlet entitled, 'A Simple Method of Water Analysis.' If, even after a careful and complete chemical and bacteriological analysis, it is sometimes difficult, even impossible, to offer a definite opinion on a water, and if one is still more often unable to say anything definite about a partial chemical examination, is it not possible, nay probable, that results obtained in the manner described in the pamphlet referred to will in most cases be misleading, and tend to do anything but raise the opinion of lay persons as regards the value of water analysis?

A welcome section is that on the bacteriological analysis of water; we know that the author has gone to considerable trouble to sift the apparently conflicting mass of literature on the subject, and favoured as he is with great opportunities for comparing the results of his laboratory work with the knowledge obtained from inspection of the sources of waters, he should be in a position to indicate to those not so favoured what are the best and most trustworthy methods. We have performed the bacteriological analysis described in the book, and we confess ourselves indebted to Dr. Thresh for the schemes he suggests for the search for *B. coli communis*. The subject is, however, capable of being greatly developed, as it is yet in its infancy, but we think that the author has to a great extent justified his claim as to the merits of bacteriology applied to the examination of waters. There are nineteen plates dealing with the microscopical examination of water, and a feature of these is that they are mostly drawn from actual sediments met with in the course of the author's practice, and the reader is informed of the source of the deposits and sometimes of the conclusions the author has been enabled to draw from them. The book is closed by formulæ for solutions and culture media, and by notes on "Detection of Radium in Water," "Helium in Spring Waters," "The Temperature of Water," "The New Turbidimeter," "Copper in Water," "Uncertainty of Deep Well Borings," "Value of Systematic Examination of Public Supplies," and "The Question of Standards." We have little but praise for this volume, which will doubtless receive the wide appreciation it deserves.

### British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

#### XIV.—BUXTON.

BUXTON lies in and on the sides of a hill-surrounded valley in the north-west corner of Derbyshire in the High Peak district. It claims to be the highest town in England, and is 1,000 feet above sea-level. The subsoil is of limestone and millstone grit. The average mean temperature is about 47° F.; the rainfall about 51 inches; and the mean relative humidity is about 83 per cent. The air is peculiarly bracing, and even in summer the place is never unpleasantly hot. The water supply is excellent, and is derived from the grit-stone formation. The sanitary arrangements are good. Exceptionally attractive provision is made for the amusement and recreation of visitors. Buxton with Bath shares the distinction of being one of our chief thermal spring stations. The waters have a uniform temperature of 82° F. They contain nitrogen gas in solution, much  $C_1$  (carbonate of calcium), and numerous other salts in small quantities. (a)

Various forms of baths can be enjoyed at Buxton, and much benefit is experienced by many patients from drinking the waters, which are particularly suitable for cases of gout, rheumatism and rheumatoid arthritis. Almost all so-called "rheumatic" conditions are benefited by a course of the waters and suitable baths, particularly lumbago, sciatica, neuritis and neuralgia, forms of synovitis, cystitis, chronic

cases of glycosuria and some varieties of eczema and psoriasis.

Some chronic dyspeptics and hepatic cases are relieved. Not a few sufferers from chronic constipation, obesity and lithiasis improve much at Buxton.

For the after treatment of sprains, dislocations and fractures, and as a recruiting station after malaria, plumbism, and certain acute disorders, Buxton presents many advantages. Many nervous cases do well, and the place is well suited to the needs of certain neuroasthenics.

Buxton is not suited for cases marked by much debility. The waters and baths are contra-indicated in pyrexial cases, advanced lung and heart affections, when there is extensive renal disease or a tendency to plethora and cerebral hyperæmia. (a)

Buxton offers facilities for all classes. The well-to-do may find every comfort in the admirable hotels and hydropathic establishments, while the poor may enjoy the benefits of the place at the Devonshire Mineral Water Hospital, which affords accommodation for 300 patients. Buxton also has the advantage of being surrounded by country peculiarly attractive and well fitted for the requirements of the health seeker.

Efforts are now being made to develop Buxton as a winter resort. It is 163 miles from London, but can be easily reached by through carriages in a little over four hours (Midland Railway).

PARIS, October 8th, 1904.

#### HYPERÆMIA IN THE TREATMENT OF ARTICULAR DISEASE.

SOME years ago Dumreicher published a case of pseudarthrosis cured by venous hyperæmia, and a short time afterwards Heferich, at the Surgical Congress, highly recommended this method in the same circumstances. Habbs towards 1885 had in the same way obtained remarkable results in cases of fracture where union was retarded. But it was in 1892 that Bier made his first communication on the treatment of surgical tuberculosis by venous hyperæmia. Relying on the cases of Rokitsansky as regards the immunity from tuberculosis of hyperæmiated tissues, he produced artificial hyperæmia in the limbs of individuals suffering from local tuberculous disease. He provoked the venous congestion by winding an elastic bandage around the central portion of the diseased limb, and left it in place several days, and even several weeks. A notable improvement was observed in the majority of cases.

Since then, Bier has published several papers on the subject modifying his method, which is now as follows:—Above the seat of the disease an elastic bandage or simply a flannel is applied. The compression must be sufficient to close the veins without affecting the arterial circulation. In order not to injure the subjacent tissues, it is sometimes necessary to use a large bandage or to interpose a slight layer of cotton wool. At each new application it is prudent to change the place of the bandage a little in order to avoid possible muscular atrophy. If the bandage is properly applied the periphery of the part swells, becomes of a bluish colour, and œdema appears; if this colour is not observed, the compression is too strong and must be eased.

The duration of the compression varies with the nature of the affection treated. If, for instance, it is a case of tuberculous disease of the joint, the bandage

(a) See "Buxton: its Waters, Baths, and Accessory Methods of Treatment," by Drs. W. Armstrong and J. E. Harburn. Bristol: Wright and Co. 1903.

(a) Consult article by the late Dr. W. M. Ord and Dr. A. E. Garrod: "The Climates and Baths of Great Britain." Vol. i, p. 528. London: Macmillan. 1895.

will be left on for four or five hours morning and evening. This treatment will be continued eight days, after which the bandage need only be applied for an hour daily. The patient should in no wise suffer from its application. The effects of hyperæmia, according to Bier, are as follows:—It relieves the pain, increases the bactericidal action of the tissues and stimulates nutrition.

Tuberculosis of the limbs and joints were the affections chosen by Bier for his experiments. Habbs tried passive hyperæmia on about 200 cases of tuberculous disease of the extremities. The results were in general very good, especially in cases that had not yet supplicated externally. A large number of chronic inflammations of the knee, the hands, and feet, which were doubtless produced by the bacilli of Koch, were so favourably influenced by the treatment that no trace of the disease could be discovered on its conclusion. Articular disease in children where the bones had not yet been affected derived unhopèd-for results from the bandage. Where the joint had supplicated, producing fistula, the treatment was much less successful. Arthritis due to gonococci, a very painful affection, leaving behind stiffness or a considerable deformity, improved rapidly by this artificial venous congestion. The pain quickly disappeared, and the after-deformity was much less than that observed by other treatments, while the function of the joint was hardly ever affected. Blecher tried the method for stiff joints after prolonged immobility, and obtained complete re-establishment of the articular function.

Bier also recommends his method in the treatment of gout, acute articular rheumatism, chronic rheumatism, chronic œdema, sprains, subacute periostitis, chronic arthritis. Hyperæmia eases pain in all these affections, and has a marked action on the absorption of exudations.

Your readers will find the following prescription of use:—

PAINFUL AFFECTIONS OF THE STOMACH.  
Stovaine (the new local anæsthetic referred to in my last), grs. x;

Syrup, ℥iv.

A teaspoonful in a little water after meals.

#### VOMITING.

Stovaine, grs. vj;

Sulph. of atropine, gr. ¼;

Hydroch. of morphia, grs. ij;

Spirits of chloroform, ℥iij q.

5 drops every 2 hours until relieved.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 8th, 1904.

At the Medical Society, Hr. Bumm discussed the SERUM TREATMENT OF PUERPERAL FEVER.

He said that as far as private practice was concerned, puerperal sepsis had not become much less frequent than formerly. This was partly due to the difficulties of effective disinfection of houses, inadequate assistance, and the circumstance that midwives were drawn from the menial classes, and partly also due to the patients themselves, who went about too long when suffering from slight hæmorrhages (miscarriages), and only called in the medical attendant when the uterine contents had already become foul. It was unjust always to put the blame on the attending midwife or nurse. We had still to fight puerperal fever. What had been recommended and done as regards washing out and even extirpation of the uterus had as yet proved ineffective. It was therefore our duty to

try a remedy that professed to strike at the root of the evil.

What prevented a united opinion being formed as to treatment by Marmorek's serum was the many-sidedness of the disease called puerperal fever. In cases of pain in general sepsis the prognosis was not difficult, and not more so in cases of purely local infection. Between these, however, lay the great number of cases that once or twice showed a high temperature with rigors, and which to our surprise recovered spontaneously. If serum had been used in such a case one was not justified in at once putting down the result to it. The speaker had principally used Aaronson's serum from Schering's factory. Careful grouping was required in estimating results.

His grouping was as follows:—

1. Septic puerperal peritonitis. Five cases treated with high doses of serum without any effect on temperature, bacterial character of the blood, or clinical course. All died.

2. Four cases of post-operative peritonitis in which there was mixed infection. All died.

3. Three cases of septicæmia. In two the blood was swarming with streptococci; these died. In the last case the temperature fell three times after injection of serum, thrombo-phlebitis of a leg took place, which terminated in recovery.

4. Three cases of septic endocarditis. All died. In one case an intravenous injection gave the impression of causing a bad result.

5. Four cases of pure pyæmia. All died. Here also there was mischief after an intravenous injection.

6. Peri- and parametric exudations. These were not treated by serum, as their onset showed that the rational way to recovery was already opened.

7. Streptococcic endometritis. Fifty-three cases. Twenty-one of these were mild cases with favourable prognosis, and were not further considered; 32 were serious cases with thick purulent deposits on the wound surface of the uterus and high fever. In 17 cases the blood was examined and in 12 streptococci were found; 5 died. In 21 cases the effect of the serum injection could always be seen on the temperature charts. This caused the subjective impression that the serum was really effective, and this impression was strengthened by objective observation. The streptococci lay in long chains between the pus cells in the lochial secretion of such cases, then short chains and many individual cocci or cocci in groups within the pus corpuscles. This phagocytosis was especially distinct after serum injection. This lent confirmation to the view that the serum supported or aided the curative powers of the organism. He had only seen harm result after intravenous injection; abscesses could be avoided by taking care that the serum was clear. It was useful in large doses only. It should be used also in cases in which from the nature of the circumstances sepsis was anticipated.

Prof. Olshausen denied that puerperal infection was as frequent as formerly; statistics were more carefully made up. It was extraordinarily difficult to decide on the value of any remedy, as the several cases with rigors occurring daily for weeks sometimes got better. He had never seen any success from Aaronson's serum, but he would continue trying.

In reply to a question by Hr. Hausemann, Hr. Bumm said that after injection phagocytosis appeared when it had been absent before the injection, and that it also appeared in the cases that went on to recovery.

Hr. Falk attributed the transient improvement seen in two cases to the injection itself, and thought that almost as much could be done by saline injection.

Hr. Freund was of opinion that the serum treatment must be continued, notwithstanding the fact that he had not with certainty seen any good from it. The speaker had done good in differentiating the various anatomical features of puerperal infection. How could it be recognised that the infection had not yet proceeded from the endometrium?

Hr. Bumm made his conclusion from inspection of the genitals, from negative examination of the blood, as well as from the absence of the usual signs of general sepsis.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 9th, 1904.

#### GUN-SHOT WOUND AND OPERATION.

AT the Prague meeting Lieblein recorded the history of a man, *æt.* 21, who was brought to his clinic in a collapsed condition, having received two shots in the breast from a revolver. The radial pulse on both sides was feeble, but Lieblein observed that the left was weaker than the right, and from this concluded that the subclavian artery on the left side was damaged, which diagnosis was confirmed the following day by a large aneurysm appearing in the infra-clavicular fossa. After this the patient seemed to improve, and nothing was done for forty hours, but a relapse having set in and the symptoms becoming ominous, operative interference was demanded. In consideration of the size and importance of the vessel he cut down and ligatured the subclavian in the super-scapular fossa. The wound was closed with tampons, and within an hour and a half after operation the patient was in a serious and exhausted condition, but afterwards recovered. Lieblein recommends this method of tying above the site of injury, as less damage is done and more security obtained.

#### METEORISM IN THE CÆCAL REGION.

Bayer discussed the present teaching in text-books of the diagnosis in the cases of closure of the large intestine. He gave it as his opinion that the meteoric distension of the cæcum was strong proof for localising the site of closure. The cæcal region was relatively weaker, but at the same time the wall of this part of the bowel had a double strain put upon it by the anti-peristaltic action of the large intestine, and at the same time a peristaltic action that met in this region. These two opposing forces produced inflation, congestion of the surrounding parts, and by the continued over-distension tore the serous part of the bowel, which soon led to gangrene and finally death. The nearer this obstruction was to the cæcum the more rapidly did the gangrene appear. Cæcal meteorism, therefore, was a reliable symptom of an obstruction in the large intestine.

Chiari agreed with Bayer in this diagnostic symbol, but thought that the cæcal wall was much weaker and had a sharp angular bend at this part of the bowel, which might, in general, be accepted as a common symptom. There were cases, however, that departed from this rule, where meteorism damaged other parts of the bowel besides the cæcum. He recently conducted a post-mortem where the meteorism was confined not to the cæcum but to the large intestine, where the distension of gas had torn the bowel in several places in the ascending colon. It might be added that the case was that of a lunatic, and that he had been throwing his hands about in such a manner as to strike the abdomen, and probably caused the rupture of the distended bowel at these places.

#### HÆMANGIOMA AND NOMA.

Springer exhibited a few cases which he had operated on with varying success. The first was a case of hæmangioma which had come in from the country. After the operation, in consequence of the bandaging a circular part of the head became necrosed through pressure, not only affecting the skin, but the muscles, periosteum and bones of the head, more particularly the frontal bones. The child had certainly been in a low condition, and the severe cachexia was probably the origin of the necrosis. The wound now is pretty well healed with an epithelial colouring, but the whole is not what was expected, notwithstanding grafting. The next case was a two-year-old boy, on which he had operated for noma that occurred on the upper lip, after an attack of measles. The morbid growth extended to the upper jaw, which he resected with the soft tissues and alveolar process. The operation had the effect of checking the further progress of the disease. He therefore commenced cosmetic operations by forming a new upper lip by taking flaps out of the under lip according to Brun's method. He exhibited another case of noma, in an adult, where the whole cheek was removed and a part of the maxillary bone resected. The meloplastic operation of Gussenbauer has now quite restored the cosmetic and functional condition of the affected part.

In the discussion that followed, the etiology of noma was examined from different points of view. Petruschky had found diphtheria bacilli in two cases of noma, which were injected into other cases and produced diphtheria, while the serum was used in the original cases with perfect success, the noma disappearing.

Ganghofner said that we were receiving daily proof that noma was not the effect of an individual bacillus, but seemed to have different causes for its origin, if not different bacilli, as the course of noma was different in its malignancy according to time and place. Within fifteen years he had seen twenty cases of noma similar to those described by Bayer on whom he had operated, with eighteen deaths. He was pleased, however, to see that the treatment by escharotics, &c., was now being abandoned for the operative method.

Springer had examined several cases of noma bacteriologically, and found in some staphylococci, in others streptococci, where inoculation failed. Removing the gangrenous parts around the growth was of no avail. The centre, though healthy, must be removed with a wide margin, as in all malignant tumours, even if the bone were affected.

### Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, October 8th, 1904.

At the latest meeting of the Interhospital Medical Association, Dr. Etvel exhibited several patients with sciatic dislocation of the hip, treated with the method first described by T. Elgart. The reducing of posterior dislocations of the hip is done as follows:—The narcotised patient is placed on the floor, his dislocated limb held over the knee of the surgeon, with the patient's knee at right angles, and the pelvis steadied by an assistant. By seizing the leg at the ankle and pressing downward the head of the femur will move upward, the surgeon's knee acting as fulcrum. Inward rotation of the femur is also practised by pushing the leg outward. With the free hand, the prominent head of the femur is seized and pressed

outward, so as to assist its gliding over the cartilaginous ring.

Salzwedel's method of treating local inflammatory processes with an alcohol compress has been modified by Beskoren in order to avoid the smarting caused by the application. He said that to this aim he adds to the alcohol an equal amount of a 1 per cent. solution of aluminium acetate, which raises the temperature of the fluid several degrees and makes it more soothing. The moistened gauze is applied directly over the inflamed area, and a piece of rubber tissue with more gauze over this. A perforated impermeable bandage is then wound around the parts.

He related also a severe case of typhoid hæmorrhage occurring in his private practice, which was virtually saved by the prompt use of adrenalin. Thirty drops of the commercial solution were given every three hours in physiological salt solution. No ill-effects were observed. Although it is improper to judge from one case, the patient had been bleeding steadily with all the other drugs.

Toxic symptoms following the use of aspirin have been already experienced and spoken of; however, the case of Frank had a peculiar interest, which rendered it worthy of emphasising. Namely, he noticed some very strange symptoms after the ingestion of one grain of aspirin. In fifteen minutes the upper lips began to swell, deglutition became painful, while pulse and respiration were very much increased. The swelling soon extended over the entire head, and was not relieved by cold applications. Somewhat later, an extremely troublesome urticaria made its appearance over the entire body. The following day all the symptoms had disappeared, and with them the attack of influenza, for which the aspirin had been given. Probably the condition was one of phenol poisoning from splitting up of the drug in the stomach, since the urine contained large amounts of phenol.

## The Operating Theatres.

### GREAT NORTHERN HOSPITAL.

**RE-EXCISION OF HIP.**—Mr. PEYTON BEALE operated on a woman, æt. about 35, who had been an inmate of the Hospital on three or four occasions, dating from the year 1887. In that year she had the head of her femur excised for tuberculous disease of the hip-joint. The wound had healed, but had broken down again, and had been scraped out several times. She now complained of several sinuses about the ischio-rectal fossa, two on the outer aspect of the hip-joint, and one about the middle of the crest of the ilium, with considerable pain both by day and night. The affected limb was about three inches shorter than the sound limb, and she was unable to put the foot to the ground. Seeing how very extensive the disease was from the number and position of the sinuses, the patient was advised that a thorough investigation should be made at the risk of a very much shortened leg, and a possible future amputation at the hip. The woman being placed on her face, a curved incision was made following the fold of the buttock, passing through the sinuses in the ischio-rectal fossa; the gluteal muscles were separated from the ilium, and the buttock was dissected up so as to form a large flap, the base of which extended from the crest of the ilium to the position of the great trochanter, care being taken of the sciatic nerves. Thus the hip-joint was exposed from behind. It was then seen that three inches of the upper end of the

femur were carious, the bone being very thin. It was therefore sawn off and removed in pieces. There were several sinuses leading into the pelvis, and there was no trace of an acetabulum to be made out. An incision was next made over and parallel to the crest of the ilium, and through it the inner aspect of the pelvis was investigated. Several pieces of necrosed bone were found and removed, and the sinuses leading through the pelvis were enlarged with a chisel and scraper so as to permit of free drainage right through. The gluteal flap was then replaced, about half a dozen sutures being inserted, and strips of gauze were placed between the sutures and in the wound over the iliac crest so as to permit of free drainage. Mr. Beale said that these cases were very painful ones to deal with, as the continuous discharge through the sinuses gradually weakened the patient, until he or she got into such a condition that scraping out the sinuses was the only thing to be thought of. This, of course, was a comparatively useless proceeding, as it was practically impossible to reach the seat of disease. He considered that it was right in the interest of the patient to attempt at any rate to reach the disease and remove it before he or she had become much weakened by long-continued discharge. The shock of such a radical operation was necessarily very severe, and it was very important that the patient should realise the risk of such an operation; but through it, at any rate, there was a chance of getting the disease away and prolonging life, whereas otherwise there was little or no hope. Such operations must always be rather risky, because vessels and nerves were found far out of their normal position, through cicatricial contraction following upon the original operation. It was necessary in this case, he pointed out, as in many others, to investigate the inner aspect of the pelvis as otherwise any necrosis in that situation could not be dealt with. After such an operation one could hardly hope for anything but a flail limb, and if the patient regained strength and the limb was found to be useless it could be subsequently removed. Of course, removal at the time, he remarked, was not to be thought of on account of the excessive shock.

### ITALIAN HOSPITAL, QUEEN SQUARE.

**IMPACTED FOREIGN BODY IN THE LOWER END OF THE ŒSOPHAGUS.**—Mr. LENTHAL CHEATLE operated on a girl, æt. 20, who had been admitted on account of having swallowed a half-crown three days previously. She was retching and vomiting, and the vomit contained streaks of blood. She vomited immediately after taking food. Examination with a bougie showed obstruction at the cardiac end of the œsophagus. A coin-catcher caught the coin, which, however, was so firmly impacted that a sufficient force of traction to remove the foreign body was not deemed advisable. After admission the temperature was 101° at night, and the pain in the chest went on increasing. Mr. Cheatle's colleague, Dr. Naumann, kindly X-rayed the case and demonstrated the coin in the gastric end of the œsophagus. The abdomen was opened in the middle line above the umbilicus, the stomach brought out on to the abdominal wall, and a curved longitudinal incision made midway between the two curvatures in the anterior wall of the viscus. The lips of the wound were held up and apart, and the gastric contents removed by means of sponges. The stomach was next put back into the abdomen, and the finger inserted into the œsophagus through the

gastric opening. The coin could just be felt. Curved laryngeal forceps were passed along the examining finger, the coin seized, and easily pulled downwards. The stomach wall was sewn up as follows:—The mucous membrane was joined by silk sutures, the muscular and peritoneal coats were brought together by Halsted's sutures. The abdominal wound was closed in the usual way. Mr. Cheatle said that as it had not been safe to leave the case any longer, for the temperature was rising, the pain increasing, and the patient starving, and as it was dangerous to endeavour to pull the foreign body upwards with the coin-catcher on account of the very firm impaction, he had no alternative but to attempt its removal from below. He pointed out that he had easily found the œsophageal opening in the stomach by passing his finger upwards along the lesser curvature of the viscus, until the œsophageal opening was reached; unless some method of this kind be adopted, the œsophageal opening is surprisingly difficult to find.

The girl went out of the hospital after a fortnight perfectly well.

### HOSPITAL ISOLATION AND SCARLET FEVER.

THIS week we publish the last of our series of papers dealing with the question of the utility of hospital isolation as a means of controlling the spread of scarlet fever. Every one of our contributors has either openly stated, or strongly suggested, his disbelief in the ability of isolation hospitals to accomplish the purpose named. For ourselves we can hardly go so far. Though convinced of the necessity of a searching inquiry into the whole matter, we cling to the belief that isolation must prevent a certain number of attacks of scarlet fever, and that by so doing the hospital system must be credited at least with accomplishing

a certain amount of good. Whether that good is commensurate with the financial outlay involved it must be confessed is open to doubt, and this would clearly form one of the pertinent questions for a Commission of Inquiry to decide. Most of our contributors have fastened on scarlet fever as the disease towards which the light of inquiry should be turned, but Dr. Marriott, who deserves the credit of having first had the courage to open up the subject of the doubtful utility of isolation hospitals, pointed out in our last issue how difficult it would be to confine attention to one disease. The considerations that militate against success for the system in dealing with scarlet fever operate in no small degree in the case of diphtheria, and there is little evidence that typhoid fever outbreaks are appreciably prevented by the conveyance of individual cases to hospital. But in the two latter maladies the therapeutic gain to the patient is undeniable, to say nothing of the virtues of strict disinfection, good nursing and careful medical supervision which are admittedly essential to the proper treatment of all but the most benign cases of diphtheria or typhoid fever. In the bulk of scarlet fever cases it cannot be pretended that nursing or physicking plays any important rôle in the recovery of the patient, and the figures presented by Dr. Hubert Biss in his first paper showing the comparative mortality-rates for home- and hospital-treated cases for London give little warrant for the assumption that scarlet fever patients in general gain much from hospital methods. Moreover, there is a large class of doubtful cases and of mixed infections which is so intimately related to scarlet fever on the one hand, and to diphtheria on the other, that no inquiry could afford to leave them out of account. In contemplating the whole matter the mind must clearly distinguish for itself the two issues—the preventive influence of the hospitals, and the machinery for individual treatment which they afford. The two questions are distinct. It is one thing to argue that the poor should be provided with accommodation for their infectious sick when this cannot be arranged for at home, and quite another to demand that *nolens volens* every one of their number who suffers from a mild attack of scarlet fever or diphtheria shall be hurried into hospital for six or eight weeks. It may be, and we are quite prepared for the conclusion, that hospital facilities should be granted—out of the rates, if need be—for practically all cases of typhoid fever, a large number of cases of diphtheria, and a proportion of cases of scarlet fever that need more care than their home circumstances can allow, but the money expended for this purpose can only be incidentally regarded as required for preventive medicine. The outlay would be primarily and justifiably eleemosynary, just as the outlay on our voluntary hospitals and workhouse infirmaries is at present. And if the three diseases named are thus provided for, why should severe cases of measles and whooping-cough be denied the same advantages? The answer is not obvious. Such a conception of the functions of a fever hospital differs entirely from that which

at present prevails, and without abolishing the institutions on which so much money has been spent, a Commission of Inquiry might find a method by which their up-keep might be made less burdensome to the community without essentially curtailing their usefulness to the sick poor. The general opinion of the medical profession has been seriously disturbed on the subject. Five years ago the isolation hospital was regarded as the one preventive measure on which no disagreement was possible, or even admissible. At the present moment all, or nearly all, our contemporaries have expressed their doubt as to its ability to accomplish its declared ends, and many medical officers of health have declared themselves in even more decided terms. Our own columns bear witness to the same fact. Although it is now seven weeks since we published the first of our series of papers, we have not heard from any of our readers that they are not in substantial accord with the position the writers have taken up—a sign we take to indicate that the matter is one on which they, too, would like the searchlight of inquiry turned. The question is undoubtedly one of great public moment. Delay and uncertainty are irritating, if not positively dangerous. After all that has been said and written, it is impossible to conceive tranquillity and confidence being restored until the matter has been sifted to the bottom.

#### "OUR VISITORS."

THE present week has witnessed a medico-social event of considerable interest, in that the medical men of London have been privileged to extend the hand of good-fellowship to a representative delegation of *confrères* from across the Channel. Although a friendly feeling between practitioners of the healing art has always existed, quite irrespective of the political outlook of the moment, this visit followed harmoniously in the wake of various other international functions of the kind engendered by the re-awakening of cordial sentiments between the two countries. We welcomed our French visitors the more because, in truth, we suspect that they, generally, are not as familiar with our medical and educational institutions as British practitioners are with theirs. One experiences a feeling of satisfaction at being enabled to show them that, although methods may differ, the study and the application of medical science are pursued with as much energy and perseverance here as on the Continent. For the familiarity of many English practitioners with French hospitals and schools we have to thank the unflinching courtesy with which the British medical tourist is received in Paris and elsewhere, especially if, in addition to his desire to extend his sphere of observation, there be added a working acquaintance with the French language. Our visitors cannot have failed to notice the decentralisation that characterises the organisation of our medical schools, societies, and charities, by the sturdy individualism that has achieved tolerably satisfactory results in spite of the friction and waste of energy inherent to this phase of evolution.

They will, we trust, carry away with them the conviction that the absence of State control is by no means incompatible with efficiency. It is to be apprehended that some difficulty was experienced in enabling them to grasp the fundamental difference between our general hospitals supported by voluntary contributions and the not less admirably equipped infirmaries provided by the Poor-law Service. Surprise may have merged into wonder when they learnt the immense field of clinical observation and study afforded by the latter is practically inaccessible to our medical students for reasons which assuredly will not appeal to them. The time at the disposal of our visitors was very short—only some three working days—but, judging from the programme, they were well filled, all the principal medical institutions of the Metropolis having received a share of attention. Nor was the social side neglected, for, apart from the private hospitality dispensed on a large scale by individual members of the profession to personal friends, various lunches and receptions were provided for the benefit of substantial fractions of the delegation, ending to-night in a banquet at the Hotel Cecil, at which a distinguished and numerous company of English medical men assemble to greet their foreign guests. A visit on these lines is quite a different matter from a formal international gathering such as a congress, the members whereof become mere inconspicuous items of a comprehensive scheme. It is to the congress what the *conversazione* is to the ordinary business of a medical society, and we should gladly see this mode of intercommunication developed. No profession rejoices in a freedom from mere geographical limitations at all comparable to that of medicine. Law and theology are virtually local institutions developed, at any rate in their form, in response to local requirements, but the objects of medicine as a curative art are the same in all places and in all ages. For this reason personal intercourse between medical men of different nationalities possesses an educational value not to be despised. We are all confronted by the same scientific problems and by the same material questions of professional existence, and nothing can be more useful or agreeable than to discuss these "across the walnuts and the wine."

#### KING'S COLLEGE HOSPITAL AND ANTI-VIVISECTION.

THE addresses at the opening of the winter sessions of our medical schools are the annual occasion of many oratorical effects. In many instances the speakers deal with subjects that lie outside their scientific life, and not infrequently the fruits of their philosophical ventures are more or less unripe, grotesque, and unsatisfactory. The address at King's College Hospital, London, was for the most part of the high order of intelligence, clearness, and knowledge that would naturally be associated with the eminent physician by whom it was delivered, Dr. Thomas Buzzard. One point of his address, however, as

reported in the general newspaper press, is of such an unusual character as to demand some amount of explanation by all who are concerned with the amenities of our common professional life. The statement in question may perhaps be capable of a satisfactory alternative reading, but, as it stands, it certainly suggests a popular appeal to a section of the public—the anti-vivisectionists—with whom the medical profession generally is at hopeless variance. It would be easy to imagine the glee with which the supporters of that particular cult will gloat over Dr. Buzzard's announcement. For years past, under the leadership of Mr. Stephen Coleridge, they have conducted a particularly venomous attack on the particular London hospitals in whose schools experiments on animals have been performed, or whose medical staffs have been either directly or indirectly connected with any such experimentation. Judge, then, of their feelings when they hear that the new hospital south of the Thames will be in future disconnected from the teaching school, which is to retain its old quarters in the old buildings. Further, to quote the words of Dr. Buzzard, "The laboratories of experimental pathology and also of neuro-pathology cannot conveniently be transferred to the new hospital, for the council and hospital staff are agreed that original researches in these subjects, which may involve experiments on living animals, shall find no place within its walls." This looks remarkably like a public declaration that King's College Hospital appeals to the public for support on the grounds that it is free from the taint of biological experiment. Within the last few years a small institution has come into being at Battersea, and has boldly declared itself an anti-vivisectionist hospital, but its claims and methods have not hitherto gained the approval of the medical profession. At such a time it is unfortunate that an institution of the standing and importance of King's College Hospital should make even a covert appeal to the public on a similar point. One of the present surgeons of that hospital, Mr. Watson Cheyne, and one of the past surgeons, Lord Lister, have been made the objects of particularly venomous attacks by the anti-vivisectionist party. After all, the partial severance of the two functions of teaching and of purely hospital work does not mean that experiments upon lower animals will not be performed if deemed necessary in connection with treatment of patients in the wards. It simply implies that any necessary experimental investigation will be conducted, not within the hospital walls, but in a sister building a mile or two away. We cannot possibly believe that the authorities of King's College in future intend to exclude all such investigations, which are required, for instance, to identify doubtful cases of tuberculosis, diphtheria, and certain other maladies due to the invasion of specific pathological micro-organisms. It is to be regretted, therefore, that a declaration of an ambiguous nature has been permitted to reach the public on a matter in which the interests of progressive medical science are so intimately concerned.

## Notes on Current Topics.

### Alcoholism and Insanity.

THE relationship of alcoholism to insanity is obviously one of the most important social problems that could be brought before the notice of the medical profession, especially in view of the recent steady increase of insanity in the United Kingdom. In another part of the present issue of THE MEDICAL PRESS AND CIRCULAR we print a valuable and suggestive letter upon this subject from the pen of a distinguished authority, to wit, Professor T. S. Clouston, of the Royal Edinburgh Asylum. From a study of the statistics of his own asylum he concludes that during the past twenty years there has been a steady increase in the number of cases of insanity due to alcoholism. That increase he found to be relatively greater among the rich than among the poor. Few who are acquainted with the inner life of our great cities will differ from Dr. Clouston in his conclusion that "our city and industrial population are drinking far too much for their health, and that if the present tendencies go on there is a bad look-out for the future of the people who are crowded into our cities." There can be no reasonable doubt that the drinking habits of the nation are responsible for a good deal of their madness no less than of many other of their ills. Wise and well-considered legislation in the direction of national temperance is one of the most urgently needed of all political reforms. Foreign wars and conquests may be necessary now and then, but the drink evil is ever within our walls, a burning and increasing danger.

### The Prevention of Malaria.

A STUDY of the discussion on the prophylaxis of malaria which took place at Oxford is bound to raise the question as to whether the present practice in anti-malarial operations is correct. Roughly speaking, the steps which are supposed to be necessary to rid a district of malaria consist in destroying the breeding-places of the *anopheles*. All marshes are to be drained, all ditches and pools emptied, and all water that cannot be got rid of covered with a coat of oil. It will be remembered that, some two or three years ago, in order to test the validity of these views, the Indian Government sanctioned a prolonged experiment at Mian Mir, the management of which was in the hands of officers of the Indian Medical Service. The experiment, which is now concluded, failed to produce any change in the fever returns, and its failure is held by some critics as a proof of the inefficacy of the methods we have mentioned. They are said, and doubtless truly, to be ineffectual against what may be called a compensatory immigration of mosquitoes. Further, it is claimed that, although the harmless mosquitoes may be considerably diminished in number by the activity of a "malaria brigade," there is but little evidence that *anopheles* are affected. As this work of destruction of breeding-places is very costly, and is not likely to be undertaken

unless there is a fair prospect of success, it is important to consider how far such criticisms are valid. It may be said at once that the Mian Mir experiment is insufficient both in scope and accuracy to lead to any far-reaching conclusion. Only a small area of ground was chosen, a ridiculously small sum of money was spent, and the locality was quite unsuitable as a site for the experiment, since an hour's rainfall in that district is often enough to fill pools and hollows which it had taken weeks to empty. A failure under such circumstances is in no way a set-off against the brilliant success in Ismailia, and in lesser degree in Sierra Leone, Lagos, Havana, and elsewhere. Ismailia has been practically cleared of malaria by the drainage of waste pools of water. Consequently, in certain places at any rate, the "malaria brigade" is still the strong arm of prophylaxis. But, nevertheless, it is not, we fear, universally applicable and in itself sufficient. *Anopheles* breed not only in stagnant pools, but in running water, and it is impossible to stop the irrigation of a country-side even to get rid of such a plague as malaria. In many districts reliance will have, for the present at any rate, to be placed on protection against the *anopheles* rather than on its destruction. At the same time, it would be a calamity if the Mian Mir episode were to bring into discredit a method of prophylaxis which in certain localities is not only useful but of preponderant importance.

#### "Live Rails" and Accidental Electrocution.

THE great increase in the number of electric railways throughout the country makes it a matter of public interest to consider their liability to accidents. From every part of the kingdom there come reports of serious burns, shocks, or even deaths due to accidental contact with the live rail or wire. It is noticeable that there is practically no danger in touching the live rail unless one is at the same time resting on the earth, for authorities state that there is probably no pressure of current that would do harm if one could be entirely insulated from the earth. Accidents occur commonly by the victim treading on the live rail or stumbling on it, or in some cases grasping it ignorantly in his hand. Where the overhead system is used it is obvious that an accident cannot occur so long as the wire is intact. If it breaks, however, its dangling end may cause serious results by establishing a circuit with someone standing beneath. It was formerly held that only currents of high voltage were likely to cause fatal results, but this view is now being abandoned. A brief contact with 2,000 volts may not prove fatal, whereas loss of life has resulted from contact with 250 volts, the ordinary current used for domestic lighting purposes. There is still some question as to the cause of death when a fatal result occurs, some observers maintaining that the death is due to respiratory, and others to cardiac paralysis. Even in cases of apparent death, animation can often be restored by the perform-

ance of artificial respiration. Professor Silvanus Thompson has called attention to the "live rail," which, he says, will be a thing of the past in a few years' time. There is no doubt of the danger of that system, but the alternative overhead plan is by no means devoid of risks, except, perhaps, in underground tunnels.

#### Preparation of the Surgeon's Hands.

THE problem how to treat the surgeon's hands so as to render them aseptic has not yet been quite satisfactorily solved in this country. The ordinary methods of scrubbing and of treating with antiseptics, although practically they seem to answer well, are certainly not free, in theory, from bacteriological objections. So much so that some surgeons deliberately use sterilised rubber gloves for themselves and their assistants. But these gloves are a great encumbrance, and though custom enables a surgeon to gain a certain amount of dexterity in them, he can never have the same skill when using them in delicate manipulations as he enjoys with the bare hand. An ingenious method has been devised by Dr. John B. Murphy, of Chicago, and it has given such excellent results in his practice, and seems so free from objection, that it may well be given a trial over here. The plan he adopts is to use a solution of rubber dissolved in benzoin solution as a pigment for the hands, and when this is painted over and allowed to set an impermeable coating is formed which neither allows the wound to be contaminated by secretions from the hands of the surgeon, nor the hands to be infected with purulent or other discharges from the patient. Dr. Murphy uses a similar solution in which acetone is the solvent for application to the patient's skin in the neighbourhood of the wound, and he is so well satisfied with both measures that he now employs them in all cases. The idea strikes us as a good one, and if it is as serviceable in practice as it sounds in theory the solution should prove a god-send to surgeons who suffer from cracked hands and horny fingers.

#### Medical "Frumps."

IF "manners makyth the man," no less surely does dress make the woman, and whether from a desire to dissociate themselves from the fashionable world, or from a determination to carry their ideas of the hygienic requirements of dress into practical operation, the early medical women certainly brought down a good deal of ridicule upon themselves by their mode of attire. Tactically this was a mistake. Clean, fresh-looking girls with neat figures and pretty costumes would have won their battle far more easily than dowdy women with sad colours and weirdly grotesque dresses. Moreover, impressions once created take long to efface. The male medical student to the public is still the rowdy, beer-drinking creature that Bob Sawyer was, and female medical students are likely to be "new" women in the eyes of the world for many a day. Miss Murdoch, in her introductory address at the School of Medicine for Women, deplored the fact that the stigma

of carelessness in dress still rested upon the woman-doctor, and urged her audience to do their best to remove it. In her view the female "medical" should be of the world as well as in it, and it will surely not need much insistence to oblige the sweet girl-graduates "not to lose touch with theatre or music; to go to parties; to go out into the world and exchange ideas with others." But there is another possibility to be faced. If the lady student dons the costume of the age and mingles freely with the giddy world there is considerable danger that she may soon find herself the subject of a *vivâ voce* examination requiring an affirmative, monosyllabic answer. And if this be given, what sort of future will there be for female medical education?

#### Wooden Heads and Wooden Legs.

THE enthusiastic "first-aider" has been the subject of a good deal of chaff in the past, but he has certainly come to stay. Still, he wants a little improvement. We pointed out recently that, admirable as much of the work of the St. John Ambulance Association is, the courses of instruction are far too short, and that though the treatment of injuries is well taught, the diagnosis of those injuries is inadequately dealt with. An accident reported near Victoria Station the other day—if true—illustrates this defect in a rather amusing manner. A Mr. Thomas, from New Brompton, arrived on a visit to the Metropolis, but either through want of acquaintance with the danger of London streets or lack of the necessary agility, he had the misfortune to be knocked down by a hansom. The usual crowd collected, and, on finding the subject of its attention unable to rise, diagnosed a fracture of the leg. A handy police constable arrived opportunely on the scene, and took the case in charge. Demanding materials for a splint, he was provided with a broom-stick, and, with the aid of a workman's saw and some readily proffered handkerchiefs he quickly manufactured a capital substitute for a "long Liston." The crowd gaped with wonder, at the ingenious constable, and murmurs of admiration arose at his promptitude and dexterity. But, alas! for human fallibility, the preparations, like those made by the town rat for his guest from the country, were doomed to futility through unexpected circumstances. While the constable worked and the crowd gaped the patient sat up, rubbed himself, and sprang on to the sound foot. Before the bystanders could recover from their astonishment and indignation the patient was nonchalantly marching up the street, gaily swinging the injured leg; it was a wooden one. It is fair to add that by another and later account a makeshift wooden leg was made out of a broom-handle by the skill and readiness of the station constable.

#### Long Hours and Nerve Strain.

THE physiology of fatigue is full of practical importance to all who lead the strenuous life, whether it be of the body or of the mind, for it is

well to be aware of the means by which nervous energy may be economised and exhaustion of the tissues staved off. It will be generally admitted that the best work is nearly always done by severe concentration of the mental powers continued for a considerable period of time. The amount of work that can be got through by steady application for a long stretch of time is surprising, though when the end is accomplished and there is nothing left to work for, reaction quickly takes place and at the end of the day the feeling of which the worker is most conscious is vexation of spirit. This applies more particularly, of course, to mental work, for mere animal fatigue resulting from hard physical toil is somewhat easier to bear. The very act of sinking into an arm-chair when one is bodily tired is in itself a pleasure, and if the mind has been comparatively unoccupied new delights are experienced in music or in an interesting book. The responsibility attached to certain higher forms of work is, in nine cases out of ten, more wearying than the performance of the actual duties themselves. Some types of mind are totally unfitted to hold responsible posts; the mere knowledge that others will be influenced by their every act, either for good or evil, would be almost enough to drive them out of their senses. Such are destined to work under the direction of others all their lives. However well balanced a mind may be, there is a limit to its working capacity, and if this limit be exceeded a breakdown must occur sooner or later. The report of the Board of Trade upon the recent collision at a North London terminus very wisely laid stress upon the hours of duty worked by a trusted signalman as being far too long for the heavy and responsible nature of the work. It is a wonder, indeed, that cases of "error of judgment" do not happen more frequently, especially if railway companies will persist in economising at the expense of servants who are continually subjected to a high degree of nervous strain.

#### Boric Acid and Kidney Disease.

MUCH has been written of late about the effects of boric acid and borax upon the body when these substances are consumed in the form of food-preservatives. As far as the stomach is concerned, it would appear that fairly large quantities of boric acid may be ingested without producing any ill effects, for as much as forty-six grains have been taken fasting without any discomfort or untoward symptoms. Some observers have found that the drug acts as a mild aperient, even when taken in the small proportion employed to preserve milk. Other foods, such as corned beef, have been known to contain as much as 3.87 per cent. of boric acid, a point of some importance in view of the fact that among certain classes of the community this is a common form of meat-consumption. It is yet debatable as to whether the borated foods endanger the public health. Fere has shown, however, that the repeated use of boric acid or borax may be accompanied by a decided risk of producing or aggravating lesions of the kidneys.

Albuminuria not infrequently follows their internal administration. Professor Charles Harrington, (a) of Harvard, has recently conducted a series of experiments in order to ascertain if the kidneys are commonly affected by a continuous diet of food preserved with boric acid. Twelve healthy male cats were selected and were placed exactly under the same conditions. Six of them received daily, for a period of nineteen weeks, varying amounts of borax. One of these animals died quite early, but the others were killed at the end of the appointed time. Of those which had received the preservative five were found, post-mortem, to be suffering from lesions of the kidneys analogous to those of subacute and chronic nephritis in man, microscopical examination of sections of the organs showing the presence of interstitial infiltration of the cortex. In view of these facts some caution is needed before we can state absolutely that boric acid is devoid of injurious effects.

#### Hygiene in the East.

HYGIENE as a science being in these countries the most modern of all, we are accustomed to regard it as if it were equally new the world over. As a matter of fact it is one of the most ancient, and from time immemorial the races of the East have practised its maxims with exactitude. We noticed in a recent medical address a casual reference to the Japanese as probably the most highly civilised race the world has ever seen, and, although the statement may somewhat stagger assent, yet, if cleanliness be the standard chosen their pre-eminence may be granted. It is doubtless due quite as much to a wish for immediate comfort as to a larger view of health that dwellers in warm climates devote so much more time to personal hygiene than is dreamt of by the populace in colder zones; but whatever be the origin of the greater cleanliness of the tropics it is interesting to note the detailed attention that has been given to it by prophets and lawgivers. Through the Old Testament we are all familiar with the elaborate ritual of hygiene which was imposed upon the Jews, though, indeed, in their migration to other climates it tends to become little less than ritual, and to lose much of its living spirit. Some of the Jewish customs, however, still universal, among them, are well founded in the laws of health, and much of the virility of that wonderful people is doubtless due to their continued observance. Such, for instance, are the practice of circumcision, and the custom of marital abstinence for a definite period after menstruation. Of great importance, too, is the rigid attention given to examination of meat intended for food, disease in any part being sufficient to condemn the entire carcass. In the chapter on water in Avicenna's work, written in the eleventh century, and probably summarising the Arab wisdom of his day, the clearest directions are given to aid one in judging good from bad water, and

boiling is recommended in all cases of doubt or suspicion. He writes sensibly of the therapeutics of pure water, and he warns against its conveyance in leaden pipes as productive of bowel complaints. It is interesting to note, too, a saying attributed to Mahomet, and well borne out by modern discovery: "If a fly fall into a drinking water-vessel, that vessel must be washed, for a fly carries disease in one of its wings."

#### Human Foot-and-Mouth Disease.

ON various occasions during epidemics of the dread disease of cattle known as "foot-and-mouth disease," infection of man has taken place. The disease is marked by vesicles and ulcers on the mucous membrane of the mouth, and when men have been attacked the disease usually has run an acute and fatal course. Apart, however, from any known connection with foot-and-mouth disease, but occurring principally among butchers, several cases of acute pemphigus of remarkable type have been noted. There was usually a severe infectious dermatitis with hæmorrhagic bullæ, having a special tendency to affect the mouth, palate, and nostrils. The course was rapid and fatal. In Boston, in 1902, following on the use of infected vaccine lymph, a series of ten cases of this type of infective dermatitis appeared, while, curiously enough, in Wakefield, in 1903, an epidemic of foot-and-mouth disease originated with the inoculation of a calf with impure virus. Though the fact that the infection in each case can be conveyed by vaccine lymph is not sufficient to establish the identity of the two diseases, yet it will be seen that there are sufficient grounds for suspecting that infectious pemphigus in man and foot-and-mouth disease in cattle are closely allied.

#### Work as a Therapeutic Measure.

AN American contemporary in a recent issue devotes an editorial article to the discussion of work as a rational method of treatment, and thinks that in recent years its efficacy has been somewhat overlooked. The importance of rest is recognised, not merely by every practitioner of medicine but, at any rate in the abstract, by nearly every patient, and elaborate systems of treatment, such as Dr. Weir-Mitchell's, based thereon have been demonstrated to be of value. On the other hand, while we often advise physical exercise as a therapeutic measure, we but rarely advise work pure and simple, and there has been no attempt to systematise a method of treatment which should have work, either physical or mental, as its fundamental principle. While there are doubtless many cases drifting into invalidism where regular and ordered work is the only restorative needed, yet we think that more often regulation of the hours and methods of working is what is required. It is rare enough to meet with anyone suffering from sheer overwork, though common to find patients broken down under uncongenial toil, and ill-regulated hours of labour, and it is in cases like these that the careful advice of the physician

(a) *Amer. Journ. Med. Sci.*, September, 1904.

may be most useful. With those suffering from sheer idleness, however, we do not think much good is likely to result from the prescription of work, unless some scheme could be devised for carrying it into effect with the same rigour as is done in the case of rest by Dr. Weir Mitchell.

#### Eye Massage.

THE anti-vivisectionists have, by their methods, unfortunately alienated the sympathy of most right thinking people, and with every desire to be fair, it is nevertheless impossible, after what has taken place in the past, to have any dealings with them now. Under the leadership of Mr. Stephen Coleridge, they have practically declared war to the knife with the medical profession, and they have carried on their campaign by the most disingenuous methods. Perhaps their latest move, the establishment of an "anti-vivisection" hospital, is the most deliberately mischievous of any of their performances, for it invites the suggestion that "vivisection" is carried on as a part of the general practice of other hospitals. No sane man can believe that they will fail to avail themselves of knowledge that has been gained by experiments on animals; indeed, it would be impossible for them not to do so. Inoculation, moreover, as a means of diagnosis, is a daily necessity in hospitals where scientific medicine is practised. Unhappily, the anti-vivisectionists have found it possible to obtain a medical staff. In the case of the eye department, they have secured the services of a Mr. Stephen Smith, who has recently set at naught the recognised usage of the profession. Having "discovered" a method of correcting defects of vision by manipulation of the eye-ball, instead of availing himself of the usual channels for submitting his method to the expert judgment of the profession, he has seen fit to describe it to a general gathering of press reporters. He is now engaged in an unedifying duel detailed at some length in the *Daily Mail*, and has nominated as his "referee" a Dr. Ettles, of the Minorities. We do not think either of these gentlemen is likely to raise himself in the estimation of his colleagues by his action, and both of them may easily do the reverse.

#### Our French Visitors.

OUR visitors are having a busy time. After the reception at the Hotel Russell on Sunday evening, at which many eminent members of the profession in London were present, the serious business began on Monday morning with a visit to the Royal College of Surgeons of England, where the visitors were received by the President in his robes, supported by members of Council. The President welcomed them to the College in French, and invited them to visit the scene of John Hunter's triumphs. Great was the admiration excited by the inspection of the museum, its extent, its symmetry, and the inimitable care with which the collection is maintained and cared for. General regret was expressed at the inadequacy of the time at the disposal of the visitors to take cognisance of the multitudinous objects of interest.

Then followed a complimentary lunch offered by the editor of the *Lancet* at the Imperial Restaurant, which was presided over by Mr. Thos. Wakley, Junr. A letter was read from Mr. Wakley, Sen., who, though prevented from being present by his advanced years, welcomed his French conferees to England and expressed the hope that if they did not add much to their medical knowledge, they would, at any rate, carry away a souvenir of the sympathy and affection which English practitioners felt for their French brethren, and he referred in touching terms to his own experience of French hospitals in days long since. Due praise was accorded by representative members of the French medical profession to the importance of the *Lancet* as an organ of professional interests. The next item was a visit to St. Bartholomew's Hospital, where the visitors were received by the members of the staff and conducted in sections through the wards and laboratories. The home-like comfort of the wards and the ample floor space accorded to each patient were much admired, and after having completed the inspection of the hospital the visitors were taken to the palatial board-room, where the portrait of Henry VIII. attracted special attention. A visit to this famous institution would obviously not be complete without a pilgrimage to that interesting old structure, the Church of St. Bartholomew, the history of which was duly narrated by the vicar and translated into French for the benefit of those who did not understand English. After dinner the visitors adjourned in large numbers to the magnificent reception organised by Dr. and Mrs. Dundas Grant at their residence in Cavendish Square, where sweet strains were dispensed at intervals by Mr. Edouard Crosse's orchestra. Mr. Walter Kirby, the Australian tenor, elicited warm applause by his rendering of several choice songs. Metropolitan practitioners were largely represented at this gathering, and the greatest animation prevailed throughout in spite of the apparently slight obstacle due to the difference of language.

#### PERSONAL.

ON Saturday last, October 8th, H.R.H. the Duchess of Albany formally opened the new operating theatre of the London National Hospital for the Paralysed and Epileptic in Queen's Square. After the ceremony the Duchess inspected the hospital.

AN address was presented to the Duchess by the Chairman of the Board, Mr. John Dundas Power, and later Sir Victor Horsley announced a gift of £1,000 to endow a table in the department of nervous diseases research.

IT transpires that the medical man who rendered such splendid service in the recent railway disaster at Llanelly was Dr. Hepburn, the well-known Professor of Anatomy in Cardiff University College.

IN one account of the accident it is stated that invaluable assistance was rendered to the injured by Mr. Harry Watkins, of Brixton Lane, London, who was travelling in the train, and who was happily unhurt.

WE regret to say that the name of Dr. W. P. Jones, of Sheffield, appears among the injured, with an

intimation that there is a fracture of the pelvis, but, happily, an early recovery is expected.

MR. FREDERICK RANSOM, a well-known citizen of Ipswich, has endowed a bed in the East Suffolk and Ipswich Hospital at a cost of £1,000.

THE annual distribution of prizes in connection with the Welsh Border Brigade Bearer Company was made by Colonel A. W. Duke, M.D., R.A.M.C., Principal Medical Officer N.W. District.

THE KING, on the recommendation of the Home Secretary, has added the name of Dr. Donkin, one of his Majesty's Commissioners of Prisons, to the Royal Commission appointed to inquire into the care of the feeble-minded.

A PRESENTATION was last week made to Dr. Albert Bradshaw, of Wattlesborough, Montgomeryshire, by friends and patients, on the occasion of his leaving the district to practise in Birmingham.

THE *Times* has announced the approaching marriage of Mr. T. Mark Hovell with the Hon. Margaret Cecilia Bateman-Hanbury, daughter of the late Lord Bateman, and sister of the present peer.

DR. J. F. J. SYKES, Medical Officer of Health for the Metropolitan District of St. Pancras, will deliver the Presidential Address of the Incorporated Society of Medical Officers of Health at 9, Adelphi Terrace, London, on October 14th next, at 5 p.m. The annual dinner of the society will be held at the Trocadero Restaurant in the evening of the same day.

LORD LUDLOW has been appointed a member of the weekly board of the Middlesex Hospital.

SIR ALFRED FRIPP, owing to the pressure of engagements, has resigned his position as a member of the Advisory Board for Army Medical Service. Sir Alfred has been a member of the Board since it was established three years ago.

THE rumour is contradicted that Sir Frederick Treves is to succeed to the office recently vacated by Sir Wm. Taylor, K.C.B., Director-General of the Army Medical Service.

SIR ISAMBARD OWEN, who has been appointed principal of the Durham College of Science, and is well known in the medical world as a professor of St. George's Medical School, has rendered excellent service to the cause of higher education in Wales. A Welshman by birth, he was some years ago appointed Deputy-Chancellor of the University of Wales.

It is announced that Dr. Blachford has been appointed medical superintendent of the Bristol City Lunatic Asylum, at Stapleton, to fill the vacancy occasioned by the recent death of Dr. Benham.

DR. MACLAREN, who has held the post of senior surgeon at the Cumberland Infirmary, at Carlisle, for upwards of thirty years, has resigned that appointment, and Dr. Lidiard, Carlisle, now becomes the senior surgeon at the institution.

SIR DYCE DUCKWORTH has been appointed to the vacancy in the offices of Medical Referee to the Treasury, and Medical Adviser to the Pensions Commutation Board, caused by the resignation of Dr. Lionel Beale, F.R.S.

THE first general meeting of the Medical Society of London will be held on Monday, October 10th, at 8 p.m., and the first ordinary meeting at 8.30 p.m. on the same day, when the President, Mr. John Langton, will deliver the opening address.

THE office of Principal of the Durham University College of Science at Newcastle-on-Tyne was rendered vacant by the death of Dr. H. P. Gurney, who was killed while mountaineering in Switzerland in August.

DR. G. A. GIBSON, of Edinburgh, will open the Winter Course of Post-Graduate Lectures in connection with the Mount Vernon Hospital, at the Central Out-Patient Department, 7, Fitzroy Square, London, with an address on "Certain Aspects of Pleurisy."

DR. ERNEST W. WHITE, for many years Medical Superintendent of the City of London Asylum at Dartford, has been granted a superannuation allowance of £1,000 per annum.

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND.

QUEEN ALEXANDRA SANATORIUM, DAVOS.—Lord Balfour of Burleigh, Chairman of the Committee for the Sanatorium, addressed the first of a series of meetings to be held in the larger Scottish towns on behalf of this institution in Glasgow, on the 5th inst. The scheme is to build a thoroughly up-to-date sanatorium, of about one hundred beds, for the benefit of patients able to pay 25s. or 30s. a week. The committee require about £50,000 for a start, and of this they have already got upwards of £6,000. The British nation was the first in Davos to have an institution of this kind at all, but others have now outstripped us, and it is hoped that the new sanatorium, in which patients can be treated for the bare cost of maintenance, will bring us level in the race again.

MURRAY'S ROYAL ASYLUM, PERTH.—The new villas for male and female patients were opened, and the new chapel dedicated on the 29th ult. Among those present were Lord Mansfield, Sir James Crichton Browne, Provost Love, Perth, and others. Murray's Asylum, opened in 1827, is one of the seven Royal asylums in Scotland. It has recently been modernised, and several new villas have been erected at a cost of over £2,000 each. The chapel has been subscribed for by patients and friends of the institution, and was erected from plans prepared by Dr. Urquhart, the medical superintendent of asylum. After the luncheon which followed the ceremony, Sir James Crichton Browne proposed the toast of the Murray Royal Asylum in a graceful speech, in which the modern treatment of the insane was contrasted with that of the old days, in which madness was regarded as demoniacal possession and sufferers from it, if not cured by exorcism, as deserving of being treated like wild beasts, starved, bound, beaten, done to death, or caged in noisome cells where they were littered on straw, exposed to cold and hunger and to nameless barbarities by their keepers, and sometimes exhibited to gratify public curiosity.

CHALMERS' HOSPITAL, EDINBURGH.—This hospital will soon be again ready for the admission of patients, it having been closed since July pending the building of a new operating theatre, the installation of special baths, and the adaptation of part of the grounds to open air treatment. The hospital owes its existence to George Chalmers, a plumber in Edinburgh, who died in 1836, bequeathing the greater part of his fortune for the erection of a hospital for the sick and hurt. The funds were entrusted to the Dean and Faculty of Advocates, who wisely allowed them to accumulate until 1861, when the building, opened in 1864, was commenced. In accordance with the desire of the testator, the wards have been divided into public or free wards, and private wards. The latter are the chief claim which the hospital has to fuller support, for they afford a means of obtaining hospital treatment to those who, too well-to-do to accept of charity, are yet unable to pay the charges of a private nursing home. During 1903, 195 patients were treated in the public and 113 in the private wards, while 2,578 out-patients were

dealt with in the waiting-room. Dr. Muirhead is physician to the hospital, and Mr. H. J. Stiles succeeds Sir P. H. Watson in the post of surgeon.

#### BELFAST.

THE MEMORIAL TO DR. McKEOWN.—A circular letter has been issued by the committee in charge of the proposed memorial to Dr. McKeown, showing that subscriptions amounting to about £100 have been received, and asking for further subscriptions. The appeal is grounded chiefly on Dr. McKeown's work as a patriotic citizen interested in educational concerns. After detailing some of the affairs in which he interested himself, the letter proceeds:—"It is not intended that a memorial should be taken as an indorsement of all the views and all the efforts of Dr. McKeown, but as a public recognition of the very honest work of a great, truthful Irishman, who had high ideals. Dr. McKeown conceived that the relations between the State and the citizen should have the same openness, and should be marked by the same absence of underhand dealing, and of all forms of wire-pulling and back-door influence, as should mark the relations of honest friends in private life and the transactions of honest men in commerce. Whether or not his criticisms of individuals or organisations or of their methods were always accurate, it is recognised that he was in all things single-minded and steadfast, and that he spoke the truth as he thought it in his heart." These sentences indicate precisely where Dr. McKeown's weakness lay, and explain why he accomplished so little in educational affairs. Trickery and wire-pulling were perfect bogeys to him, and he saw them in every action of those who opposed him. He was of the stuff that martyrs are made of, not business men. The form which the memorial will take has not yet been decided, but it is intended that it shall be one in harmony with Dr. McKeown's public services.

THE FORSTER GREEN HOSPITAL FOR CONSUMPTION AND THE CORPORATION.—At a meeting of the city Corporation last week it was reported that the Lord Mayor and several members of the Corporation had met with the authorities of the Forster Green Hospital at a private conference, and afterwards had waited on the Local Government Board to discuss ways and means for the establishment and maintenance of a Sanatorium for consumptives. It is clear from this that there is some truth in the reports that have been circulated, that the Corporation is considering the possibility of taking over and enlarging the Forster Green Hospital, instead of building a new one for the city.

#### ALCOHOLISM AND INSANITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I entirely agree with your remarks in your issue of this date (October 5th) as to the difficulty and fallacy of attempting to assign with definiteness all the causes of any case of mental disease. But in most cases we can by careful inquiry ascertain the chief immediate or exciting cause of an attack. No doubt in very many instances the patient's brain had been in so unstable a state that a very slight cause indeed would be sufficient to produce the final and marked mental upset for which the patient had to be placed under treatment in a mental hospital. When alcohol becomes a chief etiological factor of insanity I think it is very important from a social point of view that special attention should be directed to the fact, because it is to a large extent a preventable cause. We all know that unstable and hereditarily weak brains are those that are most liable to the alcohol craving, and when poisoned by excess of the stimulant they are specially apt to be upset in their mental working. I think that such persons should all be made to know the risk they run from alcohol. In fact,

those risks should be made a part of their school education, and the duty of avoiding them be instilled into their consciences. At present many persons sin in this way through ignorance. Hence I and others, notably Dr. Conolly Norman, of Dublin, Dr. Parker and Dr. Marr, of the great Glasgow asylums, who see much of alcoholic insanity, look on it as a duty to accentuate the facts in our reports and spread as widely as we can our inferences from these facts. As you well know, the effects of alcohol on the brain are far more accurately observed now than they were some years ago, and we can speak, therefore, with more dogmatism and authority on the point.

Now, when we find that alcoholic insanity is increasing in our institutions, that it is in the city asylums where that increase is most seen, and that within a few years past the figures are really alarming, I think you will agree with me that we should fail in our duty if we did not draw the attention of our profession and the public to the matter by every means in our power.

As to the statistics of the Royal Edinburgh Asylum in regard to alcoholic causation of mental disease, they are very striking. As is well known to the profession, alcohol may act as a cause of an attack of ordinary insanity, or it may produce a true "alcoholic insanity," accompanied by characteristic symptoms such as vivid hallucinations, pareses, neuritis, &c. I find that 40 per cent. has to be taken off the whole number of cases in which the alcohol has been a distinct exciting or predisposing factor to get the number of cases of true alcoholic insanity. Treating our statistics in this way, so as to put them on a scientific basis and to eliminate error, I find that for the ten years 1874-83, 12 per cent. of the admissions of both sexes were cases of alcoholic insanity; that for 1884-93 they amounted to 13 per cent.; for 1894-1903, 17.5 per cent.; and for 1903, 23 per cent. The gross alcoholic percentage of 42.3 for the men for 1903, to which you refer, reduced to 28 per cent. of true alcoholic insanity, perhaps represents an exceptional year, but it is a fact, and is on the whole on all fours with the Dublin and Glasgow statistics for 1903. The gross alcoholic percentage in the male admissions of the two great Glasgow asylums at Gartloch and Woodilee for 1903, was 33.9 per cent. of the admissions. The last English Blue Book shows that for the whole of England and Wales the male pauper admissions showed an alcoholic percentage of 23.7 for the past five years, this including the country asylums, as well as those of the large cities. In the rural and non-manufacturing districts, the percentage is not nearly as great as this, leaving a much larger amount for the cities. In the Montrose Asylum, accommodating the rural part of Forfarshire, the percentage for both sexes for 1903 was only 8. The last Irish Blue Book showed for 1903 a percentage of 10.5.

Our statistics of general paralysis for the past thirty years confirm the general inference that drink and syphilis, for they go together largely in this country, are increasing in our cities. It has risen from 6 to 13 per cent. in that time.

Our statistics and those of the English Lunacy Blue Books—the Scottish Blue Books do not as yet give complete etiological statistics of the admissions to asylums—seem to show that neither alcoholic insanity nor general paralysis are as common in the private class of patients as among the rate-paid. In our Craig House department for the more wealthy private patients we had only 9 per cent. of alcoholic admissions for 1903. In England the private class for the five years 1898-1902 showed only 12.9 per cent. of alcoholic causation for both sexes, against 16.35 among the paupers.

I am well aware that "figures may be made to prove anything," and that we have as yet no exhaustive statistical inquiry to throw light on this grave social question. But I contend the figures I have quoted do make out a strong *prima facie* case for the conclusion that our city and industrial populations are drinking far too much for their brain health, that their brain resistiveness against the

evil effects of alcohol is lessening, and that if the present tendencies go on there is a bad look-out for the future of the people who are crowding into our cities, and who, in spite of improved sanitation and a lessened death-rate, do not seem to be acquiring the self-control especially needed to resist the temptations and dangers of an urban life. There is no single agent that can do their mental condition so much harm in the circumstances in which they are placed as excess of alcohol, and none that will affect their progeny so badly in mind and body. The process of acclimatisation of a man or woman bred in the country to a city life and environments is a dangerous one; certain bad results show themselves at once, while others take years to do so. Alcoholic insanity seems to be one of the latter kind.

I am, Sir, yours truly,

T. S. CLOUSTON, M.D.

The Royal Edinburgh Asylum,  
October 5th, 1904.

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whatever bearing upon this question Dr. Woods Hutchinson's article (referred to by a correspondent in THE MEDICAL PRESS AND CIRCULAR of this week) may possibly have is not apparent in the quotations cited. All living creatures lower in the scale than man are controlled by natural forces against which they do not contend by action based upon knowledge and reason. Civilised mankind alone have obtained the power to mould as they please their physical and moral development. The type of future man which shall predominate is capable of production with as much certainty as the breeder of horses, cattle or dogs can produce in time creatures of the type adapted best to his purposes. Creatures below the level of man do not sin, they have no vices; men are sinners, vast masses of them are full of vice or are at best permeated by a narrow selfishness, by an egoism which subordinates every consideration to the desire for a life of ease and "pleasure" for themselves and those they love. "Let us eat, drink, and be merry, for to-morrow we die." "What has posterity done for us that we should sacrifice for posterity?" These sayings express the sentiments of decadent civilisations. If such ideas triumph as they are doing in France and seem likely to do throughout the other races of modern European origin, the doom of these nations is sealed. The Yellow Peril may in time become a reality, and if after the lapse of a few centuries Macaulay's New Zealander be not found contemplating the ruins of London from a broken arch of the bridge, the glory of the Empire may none the less have departed, and the world's dominion fallen from the hands of the Anglo-Saxon into those of a more vigorous and wise, albeit, perhaps, an Asiatic people.

I am, Sir, yours truly.

A STUDENT OF SOCIOLOGY.

October 5th, 1904.

#### WHOOPING COUGH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an article on the "Bacteriology of Pertussis" (October 5th, 1904), I find the following: "Moreover, for generations it has been recognised as infectious, and no observation has thrown any doubt on this belief." May I correct this statement in the briefest manner. When I joined the Hospital for Sick Children in Great Ormond Street it was the opinion of the majority of the staff that whooping-cough was a nervous disease, and the view of Dr. Niemeyer was entertained by many. In a letter to the *Lancet*, January 3rd, 1898, I mentioned how Sir Thomas Watson had changed his views of the disease, and in a paper read before the Medical Society and published in Vol. V. of its *Transactions*, I endeavoured to show how Cullen was wrong in classifying whooping-cough along with asthma as a spasmodic disease. I remember well meeting my old friend the late Dr. Sturges one day in St. James's Park, when he said he was coming round to my view that

whooping-cough was infectious. Dr. Niemeyer's view that a birch-rod was a good remedy will give some idea of German pathology. I am rather amused to find articles in our medical journals winding up with some such name as Manicatide, or Czaplewski, and I hope that THE MEDICAL PRESS AND CIRCULAR will keep clear of this curious weakness.

I am, Sir, yours truly,

ROBERT LEE.

October 7th, 1904.

[We thank Dr. Lee for calling attention to this fact. There is no doubt that the "birch-rod" standpoint was the accepted one some twenty or thirty years ago. Dr. Lee first insisted on the infectious nature of whooping-cough. His conclusion was based on clinical grounds, and a study of 3,000 cases. An interesting account of his researches will be found in the *Lancet* January 3rd, 1898.—ED.]

#### Obituary.

EDWIN HAWORTH, M.B., C.M.Glasg.

WE regret to announce the death of Dr. Haworth, M.B., C.M., medical officer of health for Oswaldtwistle, near Accrington, Lancashire, in his fiftieth year. He leaves a widow and three young children. He was educated medically at the University of Glasgow, where, in 1879, he graduated M.B. and C.M.

DAVID ROBERT JONES, L.R.C.P.Ed., L.M.

MR. DAVID ROBERT JONES, one of the best-known public men in North Wales, died at his residence, Corwen, on September 30th. For upwards of a quarter of a century he had been chairman of the Corwen Board of Guardians. He was a native of Bala, was justice of the peace for Merioneth, a member of the governing body of Bala County School, and held many other public offices. He was a prominent Churchman, and leader of the local Conservative party. His medical education was conducted in Dublin, whence in 1870 he took the qualification of L.R.C.P.Edin. and L.M.

HAMILTON HODGES, L.R.C.P.Edin., &c.

THE death is announced of Dr. Thomas Hamilton Hodges, for fifteen years parish doctor at Killin, and latterly of Yetholm and Tweedsmuir. Dr. Hodges was born at Stair in 1849, and received his medical education at Glasgow, in which city he commenced practice before removing to Killin, where he formed one of the most extensive practices in Perthshire. He was a J.P. for Perthshire. Dr. Hodges retired to Tweedsmuir about three years ago, a paralytic seizure having obliged him to practically relinquish all medical work. He took the qualifications of L.R.C.P.Edin. and L.F.P.S.Glasg. in 1873.

#### Literary Notes and Gossip.

THE *British Journal of Children's Diseases*. (Edited by George Carpenter, M.D. No. 9. Vol. i. September, 1904.)—This journal contains:—(1) A case of hydrocephalus, in which drainage of the ventricles into the subdural space was established, by C. A. Morton, F.R.C.S. In spite of the establishment of a drain on both sides of the brain, the cerebro-spinal fluid continued to collect, and the child ultimately died. (2) A case of congenital stricture of the oesophagus, by Bertram M. H. Rogers, M.D. The stricture was situated about an inch from the lower end of the oesophagus, but no account is given of its tightness nor of the structure of its walls. (3) Some of the less commonly recognised manifestations of rheumatism in childhood, by James Burnet, M.A., M.B. Among the more important of these manifestations Dr. Burnet includes tonsillitis, pharyngitis, pneumonia, psoriasis and appendicitis. Most of these conditions, he states, are benefited by salicylates. (4) On night terrors and sleep-walking, by the Rev. Arthur L. Hussey, M.A. (5) An editorial on "Delayed Chloroform Poisoning."

THE *Boston Medical and Surgical Journal*, (Vol. cli. No. 8. August, 1904.)—Two papers on hydrotherapeutic measures appear in this journal. In both of them the advantages of this method of treatment is pointed out, and in one of them, the fact is referred to that both in England and America the subject has been neglected. That, however, there are signs of the advance of this and other physical methods of treatment is plain from recent publications. Dr. E. W. Taylor, of Boston, contributes an interesting study of a case of sacral spina bifida. Anæsthesia was present over a portion of the gluteal region and over the lower part of both legs in this case. This anæsthetic area corresponded closely with the area marked out by Thortum and Head as being supplied by the sacral nerves, and differed considerably from the sacral nerve area, as described by Starr and by Kocher. The appointment of Dr. Osler to the Chair of Medicine in Oxford is referred to by the Editor. While expressing regret for his loss, the writer says that "the entire medical profession in America may well feel a certain pride in this choice for the Regius Professorship at Oxford."

*American Medicine*. (Vol. viii., No. 9. August, 1904.)—The subjects dealt with in this journal are very numerous. Among the reports of clinical cases the most interesting is "A case of fibro-myxosarcoma of the sacrum of large size successfully treated by cataphoric operations, with preservation of the sphincter," by G. B. Massey, M.D. An incision was made immediately posterior to the anus, and through this, an electrode was passed up towards the tumour, and a current as high as 1,600 milliamperes was then allowed to flow for three hours. Two applications resulted in the sloughing away of the entire tumour, together with the coccyx. The wound cicatrised, and the patient recovered. Among the "Original Articles" is a paper by Collin F. Martin, on the "injection treatment of internal hæmorrhoids." His technique, for which he claims very successful results, consists in (1) Stretching the external sphincter under nitrous oxide anaesthesia; (2) after an interval of from four to seven days a conical speculum is inserted. Into this the hæmorrhoid prolapses when the patient coughs; (3) the hæmorrhoid is washed and injected with about 7 m. of a carbolic acid solution; (4) an ichthyol suppository is then inserted. A paper on "The beneficent agency of peritoneal exudates, adhesions, aperistalsis and meteorism in peritonitis" is contributed by H. C. Wetherill, M.D. Although there may be some small grain of truth in his contentions, few practical physicians will, we fancy, agree with most of his reasoning.

*New York Medical Journal and Philadelphia Medical Journal*. (Vol. lxxx., No. 8. August, 1904.)—The Original Communications in this number include:—(1) "The management of genital sores," by E. Wood Ruggles, M.D. (2) "The best method of operation to effect a radical cure of senile hypertrophy of the prostate gland: based on the study of 150 radical operations." The author, Dr. Orville Horvitz, comes to the following among other conclusions:—(i) There is no routine treatment for prostatic enlargement. (ii) The dangers of catheterism are greater than those of a radical operation, performed early. (iii) The proper time to perform a radical operation is when daily catheterism becomes necessary. (iv) In 90 per cent. of cases the gland can be removed from the perinæum. The perineal operation of Bryson is considered the operation of choice. (v) If the bladder be hopelessly disabled the results of operation are negative. (3) "The Finsen light treatment," by R. H. Stevens, M.D. The importance of securing a properly made lamp is insisted on. (4) "The etiology and treatment of arterio-sclerosis," by O. T. Osborne, M.D. (5) "Talma's operation for cirrhosis of the liver," by L. B. McBrayn, M.D. (6) "Renal insufficiency," by Antonio M. Crispin, M.D. In this paper, the author refers to the importance of making frequent

estimations of the total urinary solids excreted, in diseases of the heart and other organs. (7) "Surgery under difficulty in East Africa," by Samuel Gurney, M.D.

## Medical News.

### The Society for the Study of Inebriety.

AT the Quarterly Meeting of the above Society held on Tuesday afternoon, October 11th, HARRY CAMPBELL, M.D., F.R.C.P., President, being in the Chair, at the Rooms of the Medical Society of London, Dr. CHARLES F. HARFORD delivered an address, entitled "The Drinking Habits of Uncivilised and Semi-civilised Races," which will be found under the heading of "Original Communications," page 380.

### Jervis Street Hospital, Dublin.

THE Governors and Guardians of Jervis Street Hospital, Dublin, will meet on Monday, the 17th inst., to appoint a surgeon in succession to the late Dr. Cranny, and a physician in succession to Dr. Martin, who has resigned his post as announced in our last issue.

### St. Mary's Hospital Medical Schools.

THE list of awards of entrance scholarships at this medical school, examination held Sept. 20th and 21st, is announced as follows:—*Open Scholarships in Natural Science* (value £145), W. L. Cowardin. *Open Scholarships in Natural Science* (value 50 guineas each), E. W. Archer, A. B. Porteous, T. A. F. Tyrrell. *University Scholarships* (of 60 guineas each), C. H. Rothera, B.A., Emmanuel College, Camb.; and P. P. Laidlaw, B.A., St. John's College, Camb., and K. A. Lees, B.A., King's College, Camb. (equal). The Epsom Scholarship of £145 was awarded to T. C. C. Evans, on the nomination of the headmaster.

### The Royal Academy of Medicine in Ireland.

THE annual meeting of the Royal Academy of Medicine in Ireland will be held on Friday, the 14th inst., when, in addition to the usual election of the various sectional Councils for the ensuing year, the post of general secretary, vacant through the resignation of Mr. J. B. Story, F.R.C.S., will be filled. Three very strong candidates are in the field—Dr. Craig, Registrar of the Royal College of Physicians; Dr. Cronyn, medical officer to the South Dublin Union; and Dr. Travers Smith, physician to the Richmond Hospital. It is expected that the voting will be very close, and much interest is manifested in the result.

### Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity and Life Assurance Society was held on the 30th ult., at 429, Strand, London, W.C. There were present Dr. de Havilland Hall (in the chair), Mr. F. S. Edwards, Dr. F. J. Allan, Dr. J. Pickett, Dr. F. S. Palmer, Dr. J. Brindley, James, Dr. J. W. Hunt, Dr. St. Clair B. Shadwell, Dr. W. Knowsley Sibley, Mr. William Thomas, and Dr. Alfred S. Gubb. The records of the Society for the current year so far agree closely with previous experiences. In the first half of every year the sickness claims list was found to be heavy, while in the second half the amount of claims is always sufficiently low to leave a substantial margin on the year's working. In this way the funds of the Society have steadily grown until they now amount to over £180,000. As a considerable number of the members are permanently incapacitated and thus compelled to draw sickness pay, all the year round, a large sum is expended in providing what is practically a permanent provision for those who will never again be able to perform professional work. The letters read from those to whom this permanent allowance is made leave little doubt that this is one of the most valuable branches of the operations of the Society. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

### Royal College of Physicians of Ireland.

THE annual meeting of the Royal College of Physicians of Ireland will be held on Tuesday, the 18th inst., in the College Hall. The election of officers and

committees for the ensuing year will take place. It is expected that Dr. W. J. Smyly will be elected President in succession to Sir Arthur Macan, whose term of office has expired. The annual dinner will be held the same evening.

#### Childhood Society.

A COURSE of public lectures will be given in the Library of the Sanitary Institute, 72 Margaret Street, W., at eight p.m.:—Thursday, October 20th, "Discussion on Physical Deterioration," opened by E. W. Brabrook, C.B., F.S.A., Mrs. A. Watt Smyth, Robert Hutchison, M.D., G. E. Shuttleworth, M.D., Francis Warner, M.D.; chairman, Sir T. Lauder Brunton, LL.D., M.D., F.R.S. Thursday, October 27th, "Physical Condition of Working Class Children," by T. J. Macnamara, LL.D., M.P.; chairman, Rt. Hon. Sir John Gorst, K.C., M.P. Thursday, November 10th, "Mental Hygiene in Childhood," by T. B. Hyslop, M.D., M.R.C.P. Edin.; chairman, Sir James Crichton-Browne, LL.D., M.D., F.R.S.; Thursday, November 24th, "Education of Girls," by Miss M. E. Findlay, B.A.; Chair, Miss Alice Ravenhill.

#### Trinity College, Dublin.

THE school for the Royal Medical Services, which was started in Trinity College during the beginning of the year, and has proved so successful at the R.A.M.C and I.M.S. examinations, will commence its second session on November 7th. The object of the school is to enable Irish Medical students, who desire to adopt the Army or Navy as a profession, to prepare themselves in Ireland. Already the school has begun to attract candidates from the other side and, promises to take an important educational position, combining, as it does, clinical work with lectures and practical work, and offering special facilities for operative surgery.

#### University of Liverpool.

At a recent meeting of the Council of the University the following appointments were made in the Faculty of Medicine:—Lectureship in dermatology, Leslie Roberts, M.D.; lectureship in laryngology, John Middlemas Hunt, M.B.; lectureship in clinical pathology, E. E. Glynn, M.B.; lectureship in neuro-pathology W. B. Warrington, M.D., M.R.C.P.

#### Charing Cross Hospital Medical School.

THE following entrance scholarships have been awarded at Charing Cross Hospital:—The Epsom Scholarship (100 guineas), to Mr. L. H. Taylor; the Livingstone Scholarship (100 guineas), to Mr. C. J. Fox; the Huxley Scholarship (55 guineas), to Mr. H. F. L. Hugo; Universities Scholarships (each 72 guineas), to Mr. C. Beards and T. W. Wade. Entrance scholarships have also been awarded to Mr. L. M. Webber (60 guineas), Mr. E. S. Calthrop (40 guineas), Mr. R. G. Dainty (30 guineas), and a Universities' Exhibition of 36 guineas to Mr. J. J. S. Rowe.

### PASS LISTS.

#### The Royal University of Ireland.

*The First Examination in Medicine.*—The Examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—

*Pass.*—Charles Alexander, Edgar M. Condy, Vincent Cosgrave, John Counihan, Caroline J. Crawford, John B. Crawford, Edmund Doherty, Edward Dowling, James E. English, Charles A. Farrell, James Ferguson, B.A., Cornelius J. Halpin, Robert Harrington, William F. Hooper, George E. Hull, Patrick Keelan, Sarsfield P. Kerrigan, Caroline V. Lowe, William C. McCullough, Michael McGing, John J. McGrath, James A. McMurtry, Michael J. Mulligan, Arthur P. O'Connor (Sch.), James M. O'Connor, John P. J. O'Connor, Samuel P. Rea, John Seymour, William H. Sheffield, William S. R. Steven, Thomas Taylor, Eustace Thorpe, Verner Wiley.

*Exempt from further examination in Botany and Zoology.*—Henry A. Gillespie.

The undermentioned candidates have qualified on their answering to present themselves for the further examination for honours. Those qualified in two or

more subjects may present themselves for the Honour Examination in all subjects:—

Charles Alexander, John Counihan, Caroline J. Crawford, Edward Dowling, James E. English, Charles A. Farrell, James Ferguson, B.A., Sarsfield P. Kerrigan, Caroline V. Lowe, John J. McGrath, Michael J. Mulligan, Arthur P. O'Connor (Sch.), James M. O'Connor, Samuel P. Rea, William H. Sheffield, S. R. Steven.

*The Second Examination in Medicine.*—The examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—

*Upper Pass.*—Joseph D. Cummins, Thomas S. S. Holmes, Marshall F. Huston, John J. Kearney, Robert G. Kevin, James B. Lapsley, Michael Waldron. All the above candidates may present themselves for the further examination for Honours.

*Pass.*—Raphael N. Berman, Arthur R. Boyd, William Bradbury, Daniel Broderick, Edwin B. Brooke, Thomas G. Buchanan, Joseph D. G. Burke, Robert J. Clarke, Mary Cowley, Laurence J. Curtin, James Dewar, James Dooley, Joseph S. Doyle, William Faith, Patrick Ferris, Eleanor E. Finegan, Thomas Forsle, James B. Horgan, Arthur H. Joy, Richard G. C. M. Kinkead, Richard R. Kirwan, Robert Lavallin, Solomon Levy, Thomas P. Linehan, Wiclif McCready, Augustine P. MacMahon, George H. Martin, James F. Neary, Edward O'Reilly, William L. O'Reilly, Christopher F. X. O'Sullivan, John J. Sheil, Hans C. Swertz, Espine J. Ward.

*Exempt from further examination in Anatomy and Physiology.*—John Clarke, Charles Murphy, Alexander Stevenson.

*Exempt from further examination in Practical Chemistry.*—William Drowne, David O'Sullivan.

#### Glasgow University.

At the recent professional examinations for the degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

*First Examination.*—In Botany and Physics: John Cruickshank, Peter Russell M'Naught, Albert Rutherford Paterson. In Zoology and Physics: David Alexander Thomson, M.A. In Zoology and Chemistry: Robert Rankin Bow. In Botany: David Young Buchanan, Frank Crombie Macauley, Frank Needham Marsh. In Zoology: William Anderson, William M'Kendrick. In Physics: Walter Gilmour, John William M'Nee, William Wilson Rorke. In Chemistry: Walter Hermann Kiep, William Aikman Muir, John Young. *Second Examination.*—In Physiology: John Anderson, M.A., B.Sc. In Materia Medica and Therapeutics: Peter Mitchell, M.A. *Third Examination.*—In Pathology and Medical Jurisprudence and Public Health: William Blair Morton Martin. In Medical Jurisprudence and Public Health: Elizabeth Maud M'Vail.

The following passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

Archibald Aitchison (C.), David Anderson (C.), James George Anderson (B., P.), William Anderson (Z., C.), Thomas Archibald (B., P.), William Hunter Stirling Armstrong (B., Z.), Alexander Ballantyne (B., Z., C.), William Barr (B., P., C.), Charles Bennett (B., P.), Robert Rankin Bow (Z., C.), Charles Brash (Z., C.), William Barrie Brownlie (B., P.), David Young Buchanan (B., P., C.), John Adam Gib Burton (B.), Hector Mackay Calder (B., Z., C.), John Cameron (C.), Donald James Clark (B., P., C.), James Lang Cochrane (B.), Alexander Johnston Couper (C.), Rutherford Cramb (B.), John Cruickshank (B., P.), James Cowie Dick (C.), Charles Duguid (B.), William Hunter Duncan (Z.), Philip Figdor (B.), Robert Dunlop Black Frew (B., Z.), David Gibson (B.), Alexander Gordon Gilchrist (B., P.), Walter Gilmour (B., P.), George Stevenson Gordon (B., P.), Hugh Macvicar Gossman (C.), Edward O'Driscoll Graham (B., C.), John Granger (B., P.), George Haddow (B.), William Hamilton (P., C.), Michael Harkin (B., Z., P., C.), John Primrose Hay (B., Z.),

John M'Lean Hendry (B., Z.), Stephen John Henry (B., P.), James Hall Hislop (C.), William Alexander Hislop (B.), Colin Hunter (B.), Cochran Johnston (B., Z.), Walter Hermann Kiep (B., Z., P., C.), John Parlane Kinloch (B.), David Neilson Knox (B., P.), John Lang (B., P.), George Smith Livingston (Z.), William Charles Macartney (B.), Frank Crombie Macaulay (B., P.), Robert M'Carlie (B.), William M'Connell (B., P.), Donald M'Dougall (B., Z.), Neil MacInnes, M.A. (C.), William M'Kendrick, (B., Z.), Francis William Mackichan (Z., C.), Thomas Mackinlay (B., P.), Alexander M'Kinnon, (B., P.), John James Mackintosh (B., Z.), John MacMillan (Z., C.), Peter Russell M'Naught (B., P.), John William M'Nee (B., P.), Murdo MacPhail (B., Z., C.), Thomas Marlin (B., P.), Wm. The following passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., pathology; M., medical jurisprudence and public health):—

Andrew Blair Aitken (M.), George Allison Allan (M.), Andrew Woodroffe Anderson (P.), John Bain, M.A. (P., M.), George Thomson Bogie (M.), Charles Burns (P.), John Miller Hopkins Caldwell (P.), Donald Livingstone Carmichael (M.), Charles Game Angus Chislett (P.), John Shaw Dunn, M.A. (M.), William Gilchrist (P., M.), John Isdale Greig, M.A., B.Sc. (P., M.), William Grier (M.), John Hammond (P.), Charles Francis Dyer Hammond (P.), James Duncan Hart (M.), Frank Hauxwell (M.), Robert M'Gowan Hill (M.), Ralph Vincent Howell (P.), Alexander Hunter (P.), David Guthrie Hunter, M.A. (P., M.), James Hunter (M.), Archibald Yuill Hutchison (M.), Harry Stewart Hutchison, B.Sc. (P., M.), Arnold Ernest Jones (P., M.), George Notman Kirkwood (M.), Alexander Leggat (P., M.), Thomas M'Cosh (M.), Duncan M'Ewan (M.), John Macintyre (P.), William Macleod (M.), John M'Millan (P., M.), Hugh MacNaught (M.), Norman Smith MacNaughtan (M.), Richard Cameron Macpherson (P., M.), William Blair Morton Martin (P., M.), Robert May (P., M.), Henry Joseph Milligan (P.), Gavin Denholme Muir (P.), John Dunn Nisbet (P.), Patrick Joseph O'Hare (M.), Thomas Hood Rankin (P.), Thomas

Thomson Rankin (M.), John Reid (P.), William Rolland (M.), John Cooper Russell, M.A. (P., M.), Edward Louis Augustin Sieger (P.), Arthur Anderson Stewart (M.), Daniel Stewart (P., M.), John Logan Stewart, M.A. (P., M.), Joseph Roderick Sutherland (P., M.), Thomas Thom (M.), William Lind Walker, M.A. (M.), Alexander MacMillan Watson (P.), James Wyper (M.). *Women*: Jeannie Thomson Clark (M.), Elizabeth Maud M'Vail (M.), Jessie Deans Rankin, M.A., B.Sc. (M.), Jane Reid Shaw (P.), Mary Spence (P.), Christina Gibson Thomlinson (M.).

The following passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., anatomy; P., physiology; M., materia medica and therapeutics):—

Thomas Montgomery Anderson (A., P.), John Anderson, M.A., B.Sc. (A., P., M.), Thomas Barbour, B.Sc. (M.), William Rome Cammock (A., P., M.), George Campbell (A., P., M.), John Sowers Clark, M.A. (M.), Thomas Lawson Craig (M.), Robert Donald (A., P., M.), James Richan Drever, M.A. (A., P., M.), Richard John Driscoll (P.), James Dunbar (P.), Ernest Milne Eaton (M.), William Miller Fairlie (P.), John Ferguson (A., P., M.), Thomas Henderson Forrest (A.), James Wilfred Georgeson (A., M.), William Gilfillan (A., P., M.), Arnold Harris Gray (M.), William Towers Hardie (P., M.), Lawrence Hislop (A.), John Keys (M.), James Dunlop Kidd (M.), James Towers Kirkland (A.), Robert Wright Leckie (M.), George Ligertwood (P.), Ernest Bowman Macaulay (A.), Alexander M'Call (A., M.), Thomas M'Cricrick, M.A., B.Sc. (A., P.), William Anderson M'Kellar (A., P.), Murdo Duncan Mackenzie (A., P.), Alister Argyll Campbell M'Neil, (M.), Robert Marshall (M.), Allan Frederick Miller (A.), James Robertson Mitchell (A., P., M.), Peter Mitchell, M.A. (M.), Robert Wright Mitchell (P.), James Hogg Paul (M.), Arthur Geoghegan Paxton (A.), Daniel M'Kinlay Reid (P., M.), Murdock Mann Rodger (P.), Alfred Cecil Sharp (M.), James Charles Donaldson Simpson (A.), James John Sinclair (M.), William Smellie (M.), John Stevenson (M.), John Torrance Weir Stewart (P.), Robert Todd (A., P.), Martin Turnbull (A.), George Wallace (A.), Hugh Ferguson Watson (P.), Hugh White (A., P.), David John Williams (A., P.), Thomas Winning, M.A., (P.), Moses Youdelevitz (M.). *Women*: Jeannie Montgomery Andrew (M.), Annie Rennie Hird (P.), Katharine Robina Margaret Lucas (M.), Edith Oversby (A.), Vera Dagmar Reis (M.), Margaret Baillie Taylor (A.).

#### Conjoint Examinations in Ireland.

CANDIDATES have passed the September, 1904, Preliminary Examination as undernoted:—

*With Honours*.—Miss Harriet MacFaddin, Messrs. E. C. Deane, J. F. Gibbons, J. M. Gage, and N. Purcell. *Passed*.—Messrs. J. J. Clarke, H. Gray, J. T. Heffernan, B. Hill, H. Hunt, W. R. Kelly, C. Kelsall, E. P. McSweeney, W. R. O'Kieffe, W. P. H. Parker, T. A. Peel, C. D. K. Seaver, H. B. Smyth, P. T. Warren, and Miss C. F. Williamson. The Supplemental Preliminary Examination will be held on the 31st inst.

#### The Guild of St. Luke.

THE Annual Medical State Service in St. Paul's Cathedral, organised by the Guild of St. Luke, will take place this year on October 24th, at 7.30 p.m., when the Bishop of Southwark will preach the sermon. A choir of 300 voices, provided by the London Gregorian Choral Association, will render the music. Members of the medical profession are invited to attend in academical robes. Admission to the space under the dome will be by tickets only.

#### Public Vaccinators.

THE annual dinner of the Association of Public Vaccinators of England and Wales will be held at the Hotel Cecil, Strand, London, W.C., on Friday, October 28th, at 7 p.m. All communications should be addressed to Mr. Charles Greenwood, 1 Mitre Court Buildings, Temple, E.C.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a distinctive *Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**SLEEPING SICKNESS (Taunton).**—In 1901 trypanosomes were discovered in the blood of a European by Dr. J. E. Dutton, Walter Myers Fellow, while on an expedition of the Liverpool School of Tropical Medicine to Gambia. In consequence of this observation an expedition composed of Drs. Dutton and Todd, was sent in 1902 by the school to Senegambia to prosecute further researches in trypanosomiasis. The detailed report of that expedition was published in 1903, and contained a study of the pathogenetic trypanosomata of man and animals, several new species being described.

### "THE LAST DAYS OF SPECTACLES."

The newspaper report of a "new method" of treating errors of refraction under this heading refers to "Dr. Stephen Smith of the Antivivisection Hospital, Battersea." It is stated that the globe of the eye can be so altered by massage as to remedy defective forms and so restore normal sight. Most medical men will suspend their judgment until the case is brought to their notice through the legitimate channel of the medical societies and the medical journals.

**DR. PROCTOR.**—The "Dispensary Doctor" is not obliged to give any such certificates.—The Workman's Compensation Act of 1897 provides that an injured workman claiming under the Act shall, if required to do so by his employer, present himself for examination to a duly qualified practitioner, who is to be provided and paid by the employer. We do not know of any official scale of charges that has been drawn up for such cases.

**DR. W. DAVIES.**—We are not in a position to advise you as to the probabilities of practice in South Africa, but we learn from our contemporary *The South African Medical Record*, that it has been found desirable to open an agency department in connection therewith at Capetown, and that practices are both wanted and for disposal.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 13th.

**DERMATOLOGICAL SOCIETY OF LONDON** (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

**SOUTH-WEST LONDON MEDICAL SOCIETY** (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Paper:—Dr. de H. Hall: Errors of Diagnosis.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. J. Berry: Clinique. (Surgical.) 5.15 p.m. Dr. H. Mackenzie: Graves's Disease and its Treatment.

THURSDAY, OCTOBER 14th.

**BRITISH GYNECOLOGICAL SOCIETY** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Edge, Mr. F. Jordan, Dr. W. Duncan, Dr. Macnaughton-Jones, and others. Paper:—Mr. C. Martin: The Treatment of Severe Prolapse by Extirpation of the Uterus and Vagina.

**HARVEIAN SOCIETY OF LONDON** (Stafford Rooms, Tithebarn Street, Edgware Road, W.).—8.30 p.m. Mr. C. B. Keetley on "Plastic Surgery." (Harveian Lecture.)

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchingson: Clinique. (Surgical.) 5.15 p.m. Dr. W. J. Home: Pachydermia Laryngis.

**MOUNT Vernon HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Introductory Address:—Dr. G. A. Gibson (Edinburgh): Certain Aspects of Pleurisy. (Post-Graduate Course.)

FRIDAY, OCTOBER 14th.

**CLINICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8.30 p.m. Presidential Address. Papers: Dr. W. Harris and Mr. W. W. Low: The Cure of Infantile Paralysis of the Shoulder by Nerve-grafting (with case to be exhibited).—Mr. W. G. Spencer: Cases of Inflammation in and around the Liver.—Dr. P. D. Turner and Mr. E. Johnson: Traumatic Axillary Aneurysm successfully treated after Extravasation had occurred by Proximal Ligature.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Dr. W. J. Home: Clinique. (Throat.)

## Vacancies.

**Devon County Asylum.**—Second Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent, the Asylum, Exminster.

**Mickleover, Derby, County Asylum.**—Senior Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

**Kent County Asylum.**—Third Assistant Medical Officer. Salary £140 per annum, with board, quarters, attendance and washing.—Applications to the Medical Superintendent.

**Horton Infirmary, Banbury.**—House Surgeon. Salary £80 per annum, with board and residence in the Infirmary. Applications to the Honorary Secretary, 21 Marlborough Road, Banbury.

**West Suffolk General Hospital, Bury St. Edmunds.**—House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.

**East London Hospital for Children and Dispensary for Women, Shadwell, E.**—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Applications to Thomas Hayes, Secretary.

**Somerset and Bath Asylum, Cotford, Taunton.**—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications to the Medical Superintendent.

**Brecon and Radnor Lunatic Asylum, Talgarth, Breconshire.**—Medical Superintendent. Salary £450 per annum, with fully furnished house, coal, light, washing, and garden produce. Applications to J. H. Evans, Secretary.

**Metropolitan Asylums Board.**—Male Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications at the Office of the Board, Embankment, London, E.C.

**Darlington Hospital and Dispensary.**—House Surgeon. Salary £120 per annum, with board and lodging in the Institution. Applications to the Secretaries, 48 Stanhope Road, Darlington.

**Down District Lunatic Asylum.**—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, &c. Applications to the Resident Medical Superintendent.

## Appointments.

**ALWAY, W. R., M.B. Toronto,** Clinical Assistant to the Chelsea Hospital for Women.

**ANDERSON, A. W., M.B., Ch.B. St. And.,** has been appointed Junior House Surgeon to Liverpool Infirmary for Children.

**COPE RICARDO, M.B.C.S., L.R.C.P.,** House Surgeon to the Brighton and Hove, and Preston Dispensary, Northern Branch.

**CROSS, W. F., M.B.C.S. Eng., L.R.C.P.,** Assistant Chloroformist to St. Bartholomew's Hospital.

**ETHINGTON-SMITH, R. B., B.S. Cantab.,** Senior House Surgeon to St. Bartholomew's Hospital.

**FLAVELL, J. M., M.B.C.S. Eng.,** Clinical Assistant to the Department of Electro-Therapeutics, St. Bartholomew's Hospital.

**GUNNING, C. J. H., M.B.C.S., L.R.C.P. Lond.,** Second Assistant Medical Officer to the Kensington Infirmary.

**HORNE, W., JONES, M.D. Cantab.,** Clinical Assistant to the Department for Diseases of the Throat and Nose, St. Bartholomew's Hospital.

**HOWELL, C. M. H., M.B.C.S. Eng., L.R.C.P. Lond.,** Senior House Physician to St. Bartholomew's Hospital.

**HURDON, B., M.B.C.S. Eng., L.R.C.P. Lond.,** Junior House Physician to Bartholomew's Hospital.

**JOHNSON, W. CROSS, M.B., Ch.B. Vict.,** Honorary Physician to Pendleton Branch Dispensary of Salford Royal Hospital.

**JONES, J. M., M.D. Michigan,** Clinical Assistant to the Chelsea Hospital for Women.

**JUDSON, A. H., M.D. Toronto,** Clinical Assistant to the Chelsea Hospital for Women.

**LUDWARD, H. D., M.B., B.C. Cantab.,** Senior House Surgeon to St. Bartholomew's Hospital.

**LEWIS, J. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S.G.,** Certifying Surgeon under the Factory Act for the Brynamman District of the counties of Carmarthen and Glamorgan.

**PAINE, H. RICHARD, M.B.C.S., L.R.C.P. Lond., L.D.S.,** Assistant Dental Surgeon to the National Dental Hospital.

**SAWYER, JAMES E. H., M.A., M.D. Oxon., M.R.C.P.,** has been appointed Pathologist at the General Hospital, Birmingham.

## Births.

**McNABB.**—On October 7th, at the Royal Navy Hospital, Plymouth the wife of Fleet Surgeon D. McNabb, R.N., of a daughter.

**SELLER.**—On October 4th, at 154 Commercial Road, London, E. the wife of J. Douglas Sellar, M.B.C.S., L.R.C.P., of a daughter.

## Marriages.

**ANNING-HAIGH.**—On October 5th, at the Parish Church, Oak, Yorks, George Paul Anning, M.B.C.S. Eng., L.R.C.P. Lond., of Kirkstall, Leeds, to Clara Evelyn, elder daughter of Frederick Haigh, late of The Holme, Bramhope, now of Lyddon Terrace, Leeds.

**BATLEY-HAYLETT.**—On October 6th, at St. Mark's, Dalston, Albert Brook Batley, M.B.C.S. Eng., L.R.C.P. Lond., son of the late Joseph Batley, of Huddersfield, to Edith May, daughter of the late Albert Haylett, of Brentford.

**FOTHERBY-BARRETT.**—On October 5th, at St. John the Baptist's, Kensington, Henry Arthur Fotherby, L.R.C.P., M.B.C.S., of Headcorn, Kent, son of H. I. Fotherby, M.D. Lond., of Westhorpe Cote, Reigate, to Jane (Bee), eldest daughter of Dr. A. E. Barrett, of Holland Park Avenue, London.

**SCOTT-IRWIN.**—On Sept. 29th, at St. Mark's Church, Armagh, by his Grace the Lord Primate, assisted by Rev. C. E. Scott, Rector of Busbrooke, Dio. Cloyne, Rev. H. G. Scott, Rector of Oregan, Dio. Armagh (brothers of the bridegroom), and Rev. C. K. Irwin, rector of Brandy Dio. Armagh, (brother of the bride), James Crossle Scott, M.D. Dubl., youngest son of the late William Scott, M.D., B.C.S. Eng., of The Bawn, Aughnacloy, co. Tyrone, to Elizabeth Ensor, eldest daughter of the Ven. the Archbishop of Armagh.

## Deaths.

**BISHOP.**—On October 7th, at Edinburgh, Isabella Lucy Bishop, F.R.G.S., F.R.S.G.S., daughter of the late Rev. Edward Bird, rector of Wyton, Huntingdonshire, and widow of John Bishop, M.D., Edinburgh.

**COOPER.**—On Oct. 9th, at East Twickenham, Eliza Mary Cooper, widow of Horace Cooper, M.B.C.S., J.P., of Marlborough, Wilts, aged 84 years.

**ORTON.**—On October 7th, at Bedworth Warwickshire, Edward William Orton, M.B.C.S. Eng., L.R.C.P. Edin., aged 62.

**WRIGHT.**—On October 9th, at The Croft, Hinderwell, Yorks, Jane, widow of Alexander Wright, M.D., F.R.C.S., aged 80 years.

No. 16.

## Original Communications.

### ON THE TREATMENT OF INOPERABLE CANCER BY HYPODERMIC MEDICATION. By JOHN A. SHAW-MACKENZIE, M.D.Lond.

In the year 1902 I was first led to adopt the method of hypodermic medication in the treatment of disease. I had long taken an interest in the medicinal treatment of uterine fibroids, and for some years I had been desirous of finding a substitutive method of administering, among other drugs, iodide of potassium and iodine. When, therefore, Messrs. Merck, of Darmstadt, introduced iodopin—a combination of iodine and sesame oil—as an efficient substitute for iodide of potassium generally, and administered subcutaneously, without producing iodism, it occurred to me to adopt this method in the treatment of uterine fibroids and menorrhagia. The opportunity for treating cases in this way was shortly after kindly given me by Dr. John Shaw, at the North-West London Hospital, and together we obtained complete relief of symptoms in some cases with more or less shrinkage of the tumour, and probably, in at least one case, its disappearance. No particular local or general inconvenience follows the injections, which are given well into the intracellular tissue of the buttock in doses of 3 to 10 c.c. The treatment is a continuation of the older iodine one; only as it seems to me by a more convenient, rapid and direct method of administration of the drug. It does not confine the patient to bed or the house, nor is there apparently any disagreeable effect. In another case under my care rapid shrinkage at first, and later almost complete disappearance of a large and undoubted uterine fibroid, for which hysterectomy had been a few days before independently recommended, took place under this treatment. This patient at the time, mentioned to me that a friend of hers had obtained great benefit while abroad from hypodermic injections of iron, after large quantities of iron mixture had been taken here without apparent benefit. The preparation in this case was one of arsenic and iron; both this and various preparations readily obtained both here and abroad approximating to that of Dr. Zambelletti, of Milan. Extensive trials of these with or without strychnia have since been made by Dr. Shaw and myself, and have proved to be beneficial in certain cases of anæmia, neurasthenia and malaria. Again we made trial of various preparations of mercury, and a solution of the benzoate which I obtained from Messrs. Merck has proved satisfactory. Both the iron and arsenic, and

mercury are injected into the muscular tissue of the gluteus. It is impossible here to enumerate the many cases in which the above hypodermic preparations as well as others, as, for example, strychnine and spermin, have been singly or alternately employed, but encouraging results have been obtained in some cases of chronic endometritis, pelvic inflammation in women, rheumatoid and septic arthritis, locomotor ataxy, and improvement in one case of disseminated sclerosis.

*Hypodermic Medication in Inoperable Cancer.*—Encouraged by the results of hypodermic medication in the foregoing cases I was led to try various preparations, including the known injections of the cacodylates and of arsenic in cases of inoperable cancer, but beyond some temporary improvement in the general health, no manifest improvement was obtained. The problem was to find some preparation which would give relief. In course of time at last, decided relief, removal of pain and fœtor, with apparent arrest of disease, was obtained in two cases of inoperable cancer under the care of Colonel T. Ligertwood, C.B., M.D., in the Infirmary of the Royal Hospital, Chelsea, as already recorded by Colonel Ligertwood and myself in the July number, 1904, of the *Journal of the Royal Army Medical Corps*. The first case was a case of carcinoma of the tongue in an old soldier which was treated by hypodermic injections of soap solution originally recommended by Mr. John Holden Webb, Melbourne. The second case was that of carcinoma of the neck, treated by hypodermic injections of chian turpentine—a new method of treatment so far as we know, the drug itself having been originally introduced by the late Prof. Clay, of Birmingham, in the treatment of cancer.

Aware of disappointments with chian turpentine recorded in the past, its employment in this case suggested itself from the recollection of the complete recovery in 1891 of a case of presumed and advanced cancer of the uterus in which Colonel Ligertwood and I had recommended its internal administration, subsequently to the opinion at the time of an eminent authority (since deceased) of the hopeless nature of the case; while the combination of iodine and sesame oil in iodopin suggested a similar combination of chian turpentine for hypodermic purposes. It may be recollected that twenty-five years ago the late Prof. Clay strongly recommended chian turpentine by the mouth in the treatment of cancer, and "if permanent cure was not obtained, an amount of relief secured to patients which had not been afforded by any other plan." The treatment was condemned by others and fell into disuse, and yet the results obtained by Prof. Clay in certain cases cannot be doubted. Since the publication of the method

of hypodermic administration by Colonel Ligertwood and myself, Mr. Augustus Clay, the son of the late Prof. Clay, has informed me that he had never heard of chian turpentine being injected subcutaneously, but at the same time he remarks that he can quite understand how very much more trustworthy the treatment may become under this method. Accounting for the difference in the results which followed the internal administration of the drug by his father and others, he suggests that in all probability the explanation was to be found in the fact that the drug was unassimilated, inasmuch as large masses were passed undigested by the rectum. This was noticeable in the pill form of administration; the emulsion giving far better and quicker results. Mr. Clay asserts that he is now using the injections in a case of cancer of the rectum. The patient had previously been taking large doses of morphia, but has had none since the commencement of this treatment, and so far relief from pain has been obtained.

*Technique.*—The injections of chian turpentine are administered deeply into the subcutaneous tissues. Experience has shown that the buttock is a suitable place. Given deeply into the cellular tissue they occasion little or no inconvenience or pain. The muscular tissue itself must be avoided as injections into it cause pain and sense of tension. I prefer the "all glass" syringe made by Messrs. Burroughs Wellcome. The special features of this appliance are that it is separable into parts which, with the needle, can be sterilised by boiling first, before use. The method which I adopt, is to keep a separate needle for each patient. A somewhat stout needle is necessary. An irido-platinum needle is preferable, being not liable to break in the deeper injections into the gluteal region. The same applies to the intra-muscular injections of iron, arsenic, and mercury. The site of injection is first sterilised with some antiseptic solution; after which a piece of ice is placed upon the surface, or local anaesthesia induced. The former is a simple means of abolishing all pain of insertion of the needle, and though this may seem a minor detail, upon it depends, in many cases, a continuance of hypodermic medication.

*Dosage.*—Colonel Ligertwood and I found by experience that 5 minims of a 20 per cent. combination of chian turpentine with olive oil, obtained from Messrs. Southall Bros. and Barclay (Birmingham), is the quantity to begin with, increasing by 5 minims on alternate days up to 60 minims. In our first case there was considerable rise of temperature following the third and fourth injections of 15 minims and 20 minims respectively. Some doubt existed as to the cause, inasmuch as in subsequent cases the same has not been noticed when gradually pushed to the full. Messrs. Southall now supply the injections of chian turpentine in small stoppered phials ready for use, as well as the emulsion for internal administration.

*CASE I.*—*Carcinoma of the neck* in an old soldier in the Infirmary of the Royal Hospital, Chelsea, under the care of Colonel Ligertwood. There was a large hard fixed mass, ulcerating in places, and bleeding readily over the middle of the right sterno-mastoid, extending up towards the mastoid process, under the ramus of the jaw and over the trachea in front. The head was forced over to the opposite side, great pain was complained of, and swallowing was becoming difficult. It had commenced primarily as a pimple in November, 1903,

attributed to rubbing of the coat collar, and was evidently growing. Medical history sheet clean. Malaria in India forty years ago. Microscopic examination of a small piece taken from the edge of the ulceration proved it to be epithelioma. On January 25th, 1904, 5 minims of a 20 per cent. combination of chian turpentine in olive oil (sterilised) were injected subcutaneously into the arm, the dose being increased by 5 minims on alternate days till 20 minims were given. The third injection of 15 minims was followed by a rise of temperature to 102°, returning to normal in the morning; while after 20 minims it rose to 103·6°, necessitating reduction of the dose to 5 and 10 minims in future, once or twice a week, followed by a rise of temperature to 100° or thereabouts. Briefly, in this case all pain went from almost the first injection; the extensive redness of the surrounding surface, which reached to above the mastoid in one direction and on to the upper chest in the other, rapidly subsided, leaving a faint, purple discoloration, limited to the immediate neighbourhood of the growth; the ulceration decreased and the discharge assumed a purulent character free from all smell; the head was no longer tilted and could be moved freely in all directions, the difficulty in swallowing passed away, and at the end of a month the size had diminished astonishingly in all directions. On May 30th the tumour was about the size of a hen's egg, remaining stationary, but occasioning no inconvenience; slight further shrinkage had continued from week to week with purulent but inoffensive discharge from the ulcerated surface. The patient was in the convalescent ward and going out of doors regularly. As I have since heard through Colonel Ligertwood, he had begun to fail in August, took to his bed, and died; but though there had been some hæmorrhage at times, there was no pain or extension of growth.

*CASE II.*—On August 10th, 1904, Mr. — consulted me. He had been under several eminent surgeons and physicians in town. He was suffering from a rapidly growing pelvic and inoperable tumour which was first noticed in January last. I found a hard solid tumour filling the abdomen almost up to the ensiform cartilage, and the right thigh and leg were enormously distended. There had been already some hæmorrhage from the bladder on several occasions. He was unable to retain solid food. His wife was carrying out X-ray treatment for him in the country, but his appetite had failed; his weakness was great, and the surgeons in town had expressed the opinion that the X-rays had not arrested the growth. I wrote to his medical man in the country, suggesting trial of chian turpentine injections and also of emulsion of the same by the mouth, which he kindly agreed to carry out. August 22nd.—I heard from Mrs. — that so far the injections had worked a wonderful improvement, that his leg was softer, his appetite better and that he could retain solids. September 9th.—I again heard that he was really very much better; that the tumour had receded from the stomach in a really wonderful manner, and that he could eat solids as well as ever and enjoy them. September 10th.—His medical man wrote to me corroborating the above. September 17th.—Mr. — came up to town to-day to see me, and the general improvement is very marked. The abdomen is no longer distended but supple. The tumour has diminished astonishingly, and can be made out at level of the umbilicus, while the leg is

obviously reduced in size. October 8th.—The improvement so far is maintained.

*Hypodermic Injections of Soap Solution.*—For some years Mr. J. H. Webb, Melbourne, has been successfully treating cases of inoperable cancer by hypodermic injections of soap solution. When this fact came under my notice the first difficulty I had to encounter was that of determining the requisite strength of the solution and dosage. Unable to ascertain that the treatment had been tried by others I communicated with Mr. Webb. Meanwhile, Colonel Ligertwood and I agreed to commence with 5 minims of a 1 per cent. solution obtained from Messrs. Allen and Hanbury, increasing by 5 minims on alternate days to full dose of 60 minims every fourth day.

*Technique.*—The injections are given into the subcutaneous tissues. They were given chiefly into the outer surface of the upper part of either arm alternately or of chest in the neighbourhood of the growth. They were not altogether free from some smarting or pain, which, however, soon passes off or is obviated by previous injection of eucaine. They appeared to be more painful in the leg and in certain situations which vary individually, and which I have also noticed with other injections. Locally, the effect seems to vary from some tenderness to painful inflammatory areolæ and to lumps without suppuration. The soap solution readily passes through an ordinary fine steel needle, and the same details of syringe antiseptics and local anæsthesia before insertion of needle, are followed as previously noted in chian turpentine injections. For convenience, Messrs. Allen and Hanbury have put up for me one drachm doses of the sterilised soap solution in small stoppered bottles. These only require to be warmed before use and the solution poured into the barrel of the syringe.

The notes of cases treated by the foregoing method will be detailed elsewhere, with a fuller description of Mr. Webb's work and treatment. Amelioration was obtained in *all* of them, chiefly in the direction of decrease of tumour, diminution of foetor and discharge, and cessation of pain. The results obtained are such as to justify the hope that further experience may perhaps enable us one day to control malignant growths by hypodermic medication.

*Summary.*—From the experience I have so far gained, I am satisfied that the treatment is worthy of trial. The effects as shown in the cases recorded are diminution in the growth and removal of pain and foetor, followed by some restoration to normal nutrition as shown in the improvement in the general health of the patient. So far, these remarks apply to chian turpentine. With regard to Mr. Webb's treatment I am able to state that my experience so far with it has been attended with similar results, and the removal of some of the worst features—pain and foetor—confirms results claimed by him for this method of treatment. One case, independently testified to, is that of so far apparent cure of recurrent breast cancer, with hepatic metastasis and ascites. In neither case is it possible to assert what the precise action is of chian turpentine on the one hand or of soap on the other; and—whether Mr. Webb is right or wrong in his theory—in neither case could it have any influence on the gratifying results which have so far been gained by these methods of treatment. Despite the fact that an

extended trial is necessary in order to arrive at a definite conclusion as to the value of this plan of treatment, nevertheless I am personally satisfied that the results justify its trial in all cases of inoperable disease, and the urgency of cases of inoperable cancer has prompted me to publish these results of hypodermic medication, in order that no time may be lost in enabling others to put the treatment to a test themselves.

## THE WORK OF THE GENERAL MEDICAL COUNCIL.

G. CRICHTON, M.D.

"WHAT'S in a name?" There is not in truth a "General Medical Council." In 1858 the Medical Act was passed establishing the "General Council of Medical Education and Registration." In subsequent Medical Acts this title is carefully adhered to. The only place in the official Register where the words "General Medical Council" appear is on the page heading of the treasurer's report—evidently a proof-reader's mistake.

The primary object of the Council was to form a Register of educated and capable men, and unless a man were registered he was not to practise. The object of the Act was the public safety, "That persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." Those whom the Council registered were (1) the possessors of a diploma from a college, or (2) of a degree of a university, or (3) such as had obtained some kind of an education and had begun practice on their own account, or (4) those who were surgeons in the Army or Navy, apparently without any diploma. For the future, those only were to be registered who held a diploma or a degree, obtained after examination following on a prescribed course of education. This, and the preparation of the Pharmacopœia, were the sole concerns of the General Council at the first, and no succeeding Act has enlarged either its functions or its powers. As the test of qualification was examination, so the Council represented examining bodies rather than education. It was a council of examiners, and so it substantially remains. Every diploma-granting (*i.e.*, examining) corporation or university sent one member (some were grouped and sent half a member). They sent examiners and teachers, and do now. Not every-day doctors, competing with quacks and patent medicines, struggling with clubs, the prey of the dishonest in all ranks, and of out-patient departments and dispensaries. Even the Crown members, who might have been a leaven, have always been Court physicians and surgeons. It was, and even now is, a body of schoolmasters, and with the common failing—one would not say fault—of schoolmasters, they expect too much from their pupils; examinations tend to become more and more oppressive.

In the first half of the nineteenth century qualification for any licence was held to consist more in "walking the hospital" than in passing examinations. In preparation for the new registration, 1,000 men passed Edinburgh College of Surgeons in one year. The percentage of failures is not stated! The third class, mentioned above, who underwent some period of study and who, as pupil or assistant, picked up some knowledge of the art, but who, not having taken a licence, and, in consequence, were ineligible for registration,

lingered on for many years as the unqualified assistant. It is only a few years since, not without some unavoidable harshness, he was definitely extinguished. The examination in 1857 of the College of Surgeons of England appears to have consisted of one final—in anatomy, physiology, pathology, and surgery. A good knowledge of the bones was essential, but admittedly a man might be very ignorant of the other subjects. The examination was oral and lasted an hour, a quarter being given to each subject.

If we take up the story twenty or twenty-five years later the whole face of things is changed. One college vies with another in the severity of its examinations, and the universities strive to out-do them. The subjects for the curriculum are by this time settled, the Register is under the care of one official, a satisfactory Pharmacopœia is in constant use. Yet anyone casually glancing at the medical journals about the year 1882 would hardly accept that statement as correct, for there is a loud demand for reform. There has been scarcely a year in which reform of the Medical Council has not been advocated. But in 1882 and onward a determined effort was made by the British Medical Association. The demand for district representation was passed. A better system of education, a uniform standard of examination, were urgently needed, it was said. The representatives of the corporations stood in the way of advance. If general practitioners are represented in the Council all these reforms will immediately ensue. From about this time dates the change of name, so that, in ordinary speech, it is now called the "General Medical Council." This shows a change in the popular mode of thought. It was assumed that the Council—reformed—although the reform concerned only the mode in which its members were to be elected, would be the protector and the guardian of the general practitioner.

A Royal Commission was appointed in April, 1881, and it reported on June 26th, 1882. On April 5th of the following year a Bill was introduced into the House of Lords. Its main features were a uniform State examination for all students, the number of members to be eighteen (afterwards seventeen), and four of these to be direct representatives. This Bill passed the Lords, but was blocked in the Commons. However, in 1886, the present Act was brought in by Sir Lyon Playfair. Instead of one State examination were conjoint examinations, and five direct representatives on a body of about thirty. The object, functions, and name of the General Council were unchanged. It had to do with education, so that men and women may be fitted to be on the Register, as being well qualified to treat disease: nothing more. Matters of great public concern: The incidence of enteric during war, the health of young adults in crowded towns, or of professional importance; the favouritism and nepotism and corruption of public medical appointments, or fees to medical witnesses or from clubs, and so on: these are matters with which the Council has nothing to do. They only touch occasionally the fringe of such a question when it may be supposed to relate to "conduct infamous in a professional aspect."

The effect of "direct representation" has been undoubtedly beneficial, though indirectly so. There have resulted: (1) A fairly uniform, yet diverse system of examinations, complete as to the various subjects; surgery, medicine, and mid-

wifery, which formerly were the subjects of separate diplomas; (2) a comprehensive scheme of education with an enormous amount of practical work; and (3) a constant interest, though *ultra vires*, shown by the Council, thus reinforced in medical matters generally, both as regards the public and the profession. In addition, the question of preliminary education, which had been the subject of discussion from the first, was settled. But the settlement, after all, came from without. The schools, by their leaving, and the universities by their *matriculation examinations*, definitely fixed the amount of knowledge essential to a student entering on the study of every profession. Yet no one can doubt that the repeated discussions of the Medical Council were of the utmost value in pointing towards such a settlement. The Council chamber was indeed almost the only arena where the matter—of extreme national importance—could be freely and fully debated.

Look back over these forty-five years. The work which the General Council of Medical Education and Registration was established to perform is accomplished. There will still be examinations to visit, a Pharmacopœia to edit, an occasional defaulter to deal with. A great task has been nobly accomplished. The beneficial results will prove more lasting than brass. "But (as Plato says) since everything that has come into being must one day perish, even a system like ours will not endure for all time, but must suffer dissolution."

## THE IRISH POOR-LAW MEDICAL SERVICE. (a)

By MICHAEL MCHUGH, M.D., L.R.C.S.I.,  
Visiting Physician to St. Vincent's Hospital.

FOLLOWING the established custom on occasions such as this, I propose to take advantage of the opportunity to draw attention to what is undoubtedly the most important question affecting the medical profession in this country. I allude to the very unsatisfactory state of the Poor-law Medical Service. Public expressions of opinion on this subject have no doubt been not infrequent during the past few years, but I feel nevertheless that no apology is necessary for again drawing public attention to it. The chronic state of discontent which the dispensary medical officers have constantly exhibited, and which I shall endeavour to show is exceedingly well founded, has lately entered upon an acute stage and matters have become so critical that at one time we seemed to have come within measurable distance of a general strike of the Poor-law medical officers, a body comprising 50 per cent., roughly speaking, of the whole medical profession in Ireland.

The present dispensary system in Ireland may be said to have come into existence in 1851, when attention having been forcibly drawn to the condition of the poorer classes owing to the appalling catastrophe of the years 1847-48, the Medical Charities Act was passed. By it the Poor-law Commissioners, acting through the local boards of guardians, were authorised to divide up the whole of Ireland into dispensary districts "with due regard to the extent and population of the districts," and to employ a medical officer for the care of the sick poor in each of these divisions. Prior to the passing of this Act, although the workhouses had been in existence since 1841, the only provision for the medical treatment of the outside poor was by provident dispensaries, few and far between, supported by private subscription and helped at times by grants-in-aid from county funds. So few and isolated, however, were these dispensaries, that in the County Mayo.

(a) Introductory address delivered at the opening of the Winter Session at St. Vincent's Hospital, Dublin.

in 1836, only one of them had been established in a district measuring 72 miles by 58.

The dispensary districts formed as the result of the Act of 1851 would seem to have been parcelled out without regard to any proper system or geographical method. Wherever a provident dispensary existed on a landlord's estate it was apparently taken over as a going concern and constituted the centre of a dispensary district, whilst the intervening irregular spaces were subdivided into new dispensary districts, without any apparent regard to the convenience of the peasant, and certainly not to that of the doctor in the discharge of his duties. These districts extended and still extend in extraordinary manners, interlocked with one another in hopeless confusion, enclosing lakes, mountains, and bog areas in such a way as to render the giving of aid to the mass of the people a matter of great physical difficulty, apart altogether from the question of adequate remuneration to the medical officer.

This institution of the dispensary district and doctor, defective as it was, nevertheless marked a great improvement on previous conditions, being, on the whole, a fairly successful effort to place medical aid within reach of the poor in all rural districts; but it is important to note that, inasmuch as it placed in every outlying portion of the country a State-aided medical man, the landlord and well-to-do classes gained correspondingly and probably even more than did the masses of the people. It brought to their doors a trained medical man available for their own needs, and who otherwise would not be there, whilst the State paid him a grant in-aid. This is a consideration which, I think, should be strongly emphasised, inasmuch as it shows that it is more in the interest of the general public even than of the medical profession that the Poor-law appointments should be held not only by competent men but by the best men procurable, and consequently that this important service should be made as attractive as possible to the rising members of the profession. The desirability of this policy will be rendered even still more evident when it is remembered that the Poor-law officer is also the medical officer of health of his district, so that in this most important matter of general sanitation the well-being of the public is entirely in his hands.

As a rule, whenever a Government has to deal with the medical profession, it endeavours to wring a full and exhaustive service from the unlucky doctor. By the Act of 1851 the dispensary medical officer was bound "without further fee or reward to vaccinate all persons in his district." He was also bound to certify all dangerous lunatics, to act as sanitary officer, to visit the local Bridewell, and all without extra pay. It requires years of struggle to get these duties disentangled from the ordinary dispensary medical work, and to be paid for separately. Gradually, however, this was done and now the duties of vaccinator, registrar of births and deaths, and the others just mentioned form separate items of the doctor's duties, and are paid for separately, though it may be stated that as in other matters in making these extra payments the very strictest economy is observed.

In other respects, it may be stated generally that the status of the dispensary doctor has remained unchanged since 1851, although since that period the medical curriculum has been lengthened from three to five years, and the difficulty of entering the profession, both as regards expense, extension of studies, and severity of examinations, has been more than doubled. Fewer young men are studying for the profession and fewer qualify. Furthermore, the Army and Navy medical services have lately increased the already high inducements which they hold out to junior qualified men, whilst the action of the General Medical Council in causing the dismissal of unqualified assistants to the number of 800 in England has greatly increased the demand in that country for young practitioners—a demand which must be largely supplied by the products of the Irish schools of medicine. I have already

pointed out how desirable it is, not only in the interests of the poor but also of all the inhabitants of a given district, that an efficient and competent medical officer should be provided, and it will be evident, I think, from the foregoing that the local authorities will have, as time passes, greater difficulty in doing so. They have to compete with other public services which have adopted a levelling-up attitude, and if they are to do so with any prospect of success, they and the Government must remove the undoubted and serious grievances of which the Poor-law medical officers have to complain.

The first of these grievances is, that the salaries paid to these medical officers are far from adequate and no reasonable recompense for their arduous duties. In order to demonstrate this, I shall again avail myself of the valuable store of information collected by Surgeon-General Evatt, and made public by him in the exhaustive report which he has furnished to the *British Medical Journal*. In order to give a clear idea of the amount of work devolving on the doctor and of the entirely disproportionate remuneration given him, Dr. Evatt selects for detailed description what he describes as a typical union in a typical county. The union selected is the Antrim Union, of the County Antrim. It contains six dispensary divisions which, according to Dr. Evatt, are very arbitrary divisions, often ridiculous in shape and without logical geographical boundaries. They grew up haphazard after the famine and have never been fully and systematically considered.

The first of these districts examined is the Antrim dispensary district. This division contains twenty-one miles of territory, and a population of 5,356 persons, the area being, however, below the average for all Ireland, which is forty-two square miles. For this district there is but one medical officer, without the assistance of either compounder, midwife, or district nurse. This medical officer, in the year 1902, saw at the dispensary 648 new cases, many of which had no doubt to be treated repeatedly. He also performed the duties of dispenser, making up with his own hands all the medicines required, and kept the many statistical records. He attended at the dispensary twice weekly, and also acted as registrar of births, marriages, and deaths, receiving one shilling an entry for births and sixpence for marriages. He attended at their own far-scattered homes over this twenty-one square miles 321 fresh and separate cases of illness, cases so serious as to be unable to attend at the dispensary for outdoor treatment, and of which many, no doubt, required frequent visits, and for those he also made up the medicine at the dispensary.

For these duties the medical officer drew the magnificent stipend of £100 a year from the guardians, one-half of which was paid by the State from the central fund for reducing local taxation. He was obliged, however, to keep a horse and trap and a servant. Now the officers of the Royal Irish Constabulary have a fixed allowance for a horse, £50 a year, and for a manservant, £45 a year. If we calculate the upkeep of the trap and harness for the year at £5 we discover that this medical philanthropist did this onerous and exhausting work and received actually no wages for his labours, his pay being but equal to the expenses of locomotion.

Dr. Evatt also analyses the conditions existing in the five other dispensary districts of the Antrim Union, a very similar state of things being revealed in each case, the principal difference being that although the districts might be larger the salary was generally lower. In the case of one then, in fact, the Crumlin district, though the area amounted to thirty-five square miles, the salary was £84 19s. 9d.

Comment on such a state of affairs is surely needless. Bad as it is, however, it may be said that worse remains behind. As has been just mentioned, the average area of the dispensary districts throughout the country is given in the Local Government official statements as forty-two square miles. Of a total of twenty-two

districts in County Clare, ten have an area of fifty or more square miles, the Corofin district has an area of ninety-five, and Ballyvaughan actually one of 110 square miles. All of these dispensary districts are in the sole charge of one medical officer, though several of them contain supplementary out-dispensaries (as many as three or four of these in some cases), although they have to be attended on stated days by the same officer. In the County Mayo there are no less than seven dispensary districts of over 100 square miles in area, all, again, in the charge of a single doctor, with a salary of £100, or perhaps a little more, and rising in only one instance to £150.

It is important for obvious reasons to bear in mind the huge size of some of the Irish districts as the area affects the questions of time and expense of locomotion consumed by the doctor in visiting his patients. In many of the larger districts a second horse would be required. Happily, as Dr. Evatt has pointed out, we have a clear official ruling as to the cost of maintenance of a horse. It is laid down in official documents to be seen at the head office of the Royal Irish Constabulary. According to them the annual sum allowed for the horse is £50, and for a servant £45 to cover food and pay, adding expenses for repairs. Dr. Evatt concludes we arrive at a sum which may be considered sufficient to at once wipe out all salary for purely professional work in a majority of the Irish dispensaries, the officers of which may be therefore be said to be doing their work gratuitously.

The argument of the official governing body is no doubt that the medical officers have their private practice, and that for their public duties only a portion of their time is required. In reply to this, it may be said that when we consider the size of the districts and the obviously large amount of dispensary work done by the doctors, a very much larger amount of work is done by them than is contemplated in their salaries. Furthermore, the constant exacting orders issued to them by the Local Government Board, requisitions for reports, on drugs and other matters, make considerable inroads on their time, leaving them little leisure for private practice. Again, it must be remembered that Ireland does not possess for the most part a middle-class capable of paying for medical attendance at its market value, nor a resident annuitant class able to pay a medical man a reasonable fee. And, finally, that the abuse of the system of issuing red tickets—the historic red tickets—deprives the medical officer in very many cases of his due by requiring him to attend gratuitously persons who might reasonably be expected to be able to pay. This latter has been a long-standing grievance with the medical officers, about which much has been written and spoken. There can be no doubt as to its reality, and the simplest way of removing it, and perhaps the only solution of the difficulty, is that the power to issue red tickets shall be limited to the relieving officers.

One of the most crying scandals in connection with the administration of the Poor-law Medical Service is the absence of any settled system of retirement and retiring allowances. There is no compulsory rule granting the medical officers superannuation, no matter how long may have been their services. And, furthermore, should any superannuation be granted by the local guardians, the charge falls entirely on the local rates, though during the whole term of service of the particular officer the State paid 50 per cent. of his salary. It would be difficult to find a more glaring anomaly. The whole cost of superannuation has been thrown on the local rates, and deliberately, by special Act of Parliament, for it has been enacted that though the local board of guardians may grant superannuation with the consent of the Local Government Board, the Act contains this special proviso, that "no contribution shall be made thereto out of any moneys voted by Parliament."

Will it be believed that there is also a rule in existence which ordains that no applicant for superannuation shall have his claim for superannuation even considered

until he has actually resigned his appointment? If it were not so unjust and tyrannical it would almost appear comic. What it really amounts to is this—that after a medical officer has devoted his life and abilities to the service of the sick poor he is himself placed upon the rates and becomes the recipient practically of outdoor relief, for it is in the power of the guardians, after he has resigned his appointment, either to grant or withhold an allowance.

There are other matters, such as the granting of leave of absence, either in case of illness or for the annual holiday, or for the purposes of scientific study, which might be considered with advantage on this occasion, were it not that the limitations of time preclude me from doing so.

In conclusion, I can only advert with gratification to the fact that the claims of the Poor-law officers have of late been actively pushed and advocated, and this time by an organised body—the Irish Medical Association. This Association has made the following demands on their behalf, *viz.* :—

1. That a minimum salary of £200 per annum shall be paid to each dispensary officer.

2. That a grant of one month's holiday annually shall be made in each case, with pay for the locum tenens at the rate of £4 4s. weekly; and

3. That suitable superannuation shall be granted as a right and not as a favour.

These demands are certainly legitimate; if they are at all it is on the side of moderation, and I feel confident that the Association in putting them forward will have the support of all independent members of the profession, and of all right-thinking men among the general public. It certainly has my advocacy, and I shall esteem myself fortunate if, in directing public attention to this important question, I have helped in any way to mitigate the hardships and to ameliorate the lot of that long-suffering official, of that friend of the poor, of that good fellow, the Irish dispensary doctor.

## THE VALUE OF LABORATORY WORK IN MEDICINE. (a)

By E. WAYMOUTH REID, B.A. Cantab., M.B. F.R.S.

Dean of the Faculty of Medicine, St. Andrews University.

In his opening remarks Prof. Reid said he wished to indicate some of the services rendered to mankind by those who devoted themselves to biological experimentation. Until this method was adopted for the solution of biological problems, the ideas of the processes going on in even the simplest structures of a living thing were distinctly bizarre, so that the great healing art had no true foundation. A capital instance of that fact was to be found in connection with the organ known as the pancreas. Vesalius was content to think that it was a general support to the parts around. Landanus did not doubt it expurgated those impurities of the blood too gross to be dealt with by the ordinary organs, while Wharton said it ministered to the nerves by taking up certain of their superfluities. For nearly 200 years no one had a ghost of an idea of the true use of this structure. Then came experimental inquiry, largely at the hands of Claude Bernard, and the "general support" of Vesalius, the "cleanser" of Landanus, and the "nerve soother" of Wharton was found to be the most important organ of digestion they possessed. Not long ago, as the result of a different class of experiments, came the great discovery of an entirely different and additional function of the same organ, which no method could possibly have yielded but experimentation, and which immediately shed light on their knowledge of a terrible disease. Gall had for his time a very accurate knowledge of the structure of the brain and actually observed that loss of the power of speech

(a) Abstract of the Introductory Address at the Winter Session of University College, Dundee.

occurred after injury to a certain part of the brain. The result of his deductions was his phrenology, which lived no longer except for the foolish who would pay a shilling for a pennyworth of flattery.

**THE THYROID GLAND.**—In his own student days the lecturer on physiology told them what the thyroid gland looked like under the microscope, but that was all. A London physician, however, observed that one of the concomitants of a terrible disease was the wasting away of this structure, and it was proved by experiment that the cause of the disease was the absence of the function of this organ. The cure followed in a few years. Graftings were made, the gland material was injected under the skin, and it was found that the result was the same when the gland material was eaten by the patient. The direct result was that not only was the growth of body and mind in a certain class of otherwise hopelessly imbecile children restored, but thick-witted adults, drifting into idiocy, could again enjoy their health. But the consequences of that most vigorous department of biological experimentation, experimental pathology, were perhaps of greater interest to a general audience. Ever since the great discovery of the relationship of certain diseases to parasitic micro-organisms, and of the poisons which they brewed, this morbid physiology had attracted so many ardent students that it was now a distinct branch of knowledge. The modern treatment of wounds, consumption, diphtheria, and tetanus, and of a host of other infectious diseases was the immediate result of the laboratory zeal of the experimental pathologist. The benefits which these results had conferred, and would yet confer, upon man and animals must strike every thoughtful person who would take the trouble to master a little detail. Much of the remarkable and ever-increasing services rendered by the experimental pathologist had directly originated from his study of the conditions of experimental or artificially-produced immunity to disease in animals, and in the course of his work he had introduced them to one of the most remarkable reactions of the organism, namely, the production of what were called anti-bodies, in response to certain stimuli.

**THE IMMUNITY PROBLEM.**—This immunity problem was certainly just now without a rival in its interest to the experimental biologist. It had been clearly proved that not only power of defence could be increased, but that it could also be conferred, if absent, by Nature. The normal blood serum (blood fluid) held a number of different protective substances in small amounts, and the experimenter had discovered how to increase the amount of one of these enormously. Physiology had often stood still for want of chemical assistance, and in this great immunity problem it was beginning to be quite clear that the chemist must step in if only to save them from explanations of every newly-discovered phenomenon by the assumption of the existence of a new substance. To the biologist the discovery and study of anti-bodies was yielding the idea of specificity of cells undreamed of before. But if enough was known for practical purposes, as prophylactic and curative results indicated, of the action of anti-bodies, it could not be said that the deeper problem of the machinery of their production by the organism was yet far on the way to solution.

Professor Reid then referred to the application, from a medico-legal standpoint, of the specificity of anti-bodies in discovering whether a given quantity of blood belonged to a man or to another animal. In concluding, he said real progress must be slow, and shifting sands of working hypotheses would shift and shift again ere the bedrock upon which to build was reached.

**Royal College of Surgeons in Ireland Fellowship Examination.**

DR. R. M. SMYTH, Assistant Superintendent, Natal Government Hospital, Durban, South Africa, having passed the necessary examination, has been admitted a Fellow of the College. j

## Clinical Records.

### SIR PATRICK DUN'S HOSPITAL.

*Case of Perforated Gastric Ulcer Simulating Appendicitis.—Operation Twenty Hours Afterwards.—Recovery.*

By C. ARTHUR BALL, M.D.,

Assistant Surgeon, Sir Patrick Dun's Hospital, Dublin.

**PATIENT**, a girl, *æt.* 22, was admitted into Sir Patrick Dun's Hospital on Friday, June 9th. On admission she was considerably collapsed, but went to sleep shortly afterwards and slept for some hours; she then woke complaining of very severe pain in the abdomen. I saw her shortly after 6 p.m. She stated that she had been ill since the previous Saturday, suffering from severe pains in the lower part of the abdomen, but was able to keep at her work (a domestic servant) until Thursday evening, about 10.30, when the violent pain began, most severe in the right iliac region; this had continued ever since. On Friday she was given a hypodermic injection, and sent into hospital by Dr. Wright, in a cab from Dalkey. She had not vomited at any time during her illness, and had eaten her usual food; her bowels had moved the previous day.

**On examination.**—The patient was evidently very ill; pulse 120 and weak; temperature, 101°; she occasionally hiccoughed; the facial expression was one of a severe intra-abdominal lesion; the abdomen was distended; the muscles over the lower part were rigid; the maximum pain and tenderness was over the iliac regions, most marked on the right side; a small, acutely tender superficial area was noticed in the epigastric region; liver dulness was present. The patient was obviously suffering from acute general peritonitis, and on questioning, stated that she had never had pain after food, and had never vomited. It appeared from her history that she had probably been suffering from appendicitis since Saturday, and that an abscess in connection with the appendix had burst into the general peritoneal cavity.

I operated immediately, first making a small incision in the middle line below the umbilicus, to explore the pelvis and see if it contained pus. On opening the abdomen no free gas was noticed, but turbid fluid, free from smell, welled up into the wound; the intestines in the pelvis were inflamed, but not very acutely. The pelvic viscera were explored without finding anything to account for the trouble. An incision was then made over the appendix. It was found very long, running up behind the cæcum, with a kink in it, and two or three old adhesions; in fact, it looked like a typical "interval appendix" but was only inflamed to the same extent as the surrounding intestines, and evidently was not responsible for the peritonitis present. An incision was now made in the middle line above the umbilicus; the transverse colon was adherent to the anterior abdominal wall, and completely covered with lymph exudate; the adhesions were easily broken down and the stomach examined. A perforation was found on the anterior surface of the lesser curvature near the cardiac orifice, about one centimetre in diameter, very patent, and through which fluid poured. The induration around the perforation was so extensive that excision of the area was impossible, and sutures, passed even some distance from the perforation, cut out as soon as tied. A fold of healthy stomach wall was therefore brought over the diseased area, and sutured to the gastro-hepatic omentum, which was indurated and friable for some distance away from the stomach. This, while effectually sealing the perforation, produced a good deal of deformity; however, fluid and flatus could be easily passed from one end of the stomach to the other. The cleansing of the peritoneum was then proceeded with; the peritonitis in the upper half was much more severe than that met with in the lower part of the abdomen; the viscera in the neighbourhood of the stomach were covered with lymph

and adherent to one another. These adhesions separated easily, and the whole abdominal cavity was washed out with large quantities of saline solution, until the fluid came away quite clear.

I then considered the advisability of performing a gastro-enterostomy as recommended by Mayo Robson. It would have been very difficult, owing to the thickened and inflamed condition of the intestines and stomach, and the patient's condition was such that any prolongation of the operation unless necessary to save her life was inexpedient.

Rubber drainage-tubes were passed to the renal fossæ and into the pelvis; the upper incision was left open and packed with gauze down to the perforation; the two lower wounds were completely closed, with the exception of where the tube entered the pelvis.

The after-history of the case was uneventful; the pulse and temperature gradually fell to normal. Convalescence was prolonged by the development, some two weeks after the operation, of an abscess in the upper wound due to the *Bacillus coli communis*.

Closely questioning the patient afterwards, she admitted having suffered from indigestion last Christmas year, which lasted till the following May. She had a slight recurrence of this last Christmas. She also gives a history of two attacks of pain in the right iliac fossa which may have been appendicitis.

She left hospital on July 18th, perfectly well, the alteration in the contour of her stomach apparently causing no trouble.

The following points in the case are of interest:—

1. Twenty hours had elapsed between the perforation and the operation, during which time the patient underwent the journey of nine miles, from Dalkey, sitting in a cab, a trying ordeal which she could hardly have borne without the morphia which, by masking symptoms, was to some extent responsible for the delay in having recourse to operation.

2. As has occasionally occurred, the history and symptoms pointed to appendicitis.

3. Vomiting was absent both before and after the operation.

## Transactions of Societies.

### WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

#### NOTES ON PSYCHOLOGY.

At the opening meeting of the twenty-third session of the above Society, held at the West London Hospital, on Friday, October 7th, the President, Charles M. Tuke, Esq., M.R.C.S., occupied the chair, and delivered an address on Psychology.

The President very naturally chose the special work to which he has devoted his life for the subject matter of his address. He referred to the able address of the late President, in which he dealt with the enormous advance made in medical knowledge during the last fifty years. But, striking and real as that advance undoubtedly was, it might be asked if the *treatment of insanity* had also advanced during that time. He replied that progress had been made in that branch of medical science almost as great as in any other direction—an advance not perhaps marked by any one great discovery, but chiefly by the general adoption of a principle which had been of enormous value to thousands, and had conferred honour on those who initiated it, and also on the whole profession of medicine. This system—the non-restraint system—is now universal, but in considering the advances of medical science, its first recognition must mark an epoch, and it is almost impossible to believe that its general adoption dates from only some sixty years ago. By very interesting references to ancient history and quotations from Plato, Euripides, Hippocrates, Coelius and Galen, &c., he compared the treatment of insanity among the ancients with more modern methods, and drew attention to the surprising fact that it is not possible to trace a gradual improvement in the history of the treatment of insanity—the same story of deplorable

ignorance: neglect, cruelty, and even imprisonment in chains and burning obtaining almost universally—until the close of the eighteenth century. It was not until 1792 that the name of Pinel recalls a noble change in the whole system, fifty-three patients being liberated from chains by him in that year at Bicêtre, and the non-restraint system inaugurated in France. In England, in the same year, William Tuke founded an institution in York called the Retreat, which was conducted on lines almost identical with the non-restraint system, and it is to William Tuke and his grandson, Samuel Tuke, that so much of the credit is due in obtaining the appointment of a committee of the House of Commons in 1815 to inquire into the condition and management of asylums. From that time dates the disappearance of ignorance and cruelty, and the rise of a high standard of moral management, also the building of new asylums superintended by men of intelligence, sympathy and humanity. Lincoln Asylum (under Mr. Gardner Hill and Dr. Charlesworth) and, on a larger scale, Hanwell Asylum (under Dr. Conolly) were very conspicuous examples of the new treatment. In dealing with the laws regarding the insane, Mr. Tuke emphasised the strides made in the right direction by the Vagrant Act in 1744, and also the noble work done by Lord Ashley (afterwards Lord Shaftesbury), through whose efforts the Commissioners in Lunacy were appointed. In the 58th Report of the Commissioners the number of persons certified as insane in England and Wales on January 1st, 1904, was 117,199, a return which showed a slight annual increase at a greater rate than the growth of the population. But this increase was more apparent than real; it was almost wholly among the pauper patients, and could perhaps be accounted for by the fact that cases are now more readily recognised and certified than formerly, and also because with the improved sanitation and medical treatment, aged cases are accumulating in asylums. The provisions of the law regarding both "Chancery patients" and the "voluntary boarder" were clearly explained, and the lunacy law was shown to be very ample, both for the patient and his property. Mr. Tuke gave valuable and practical advice as to the treatment of the so-called "nerve cases," and spoke in the highest praise of borough and county asylums—their one fault, if any, being that they had become too huge. Could the medical superintendent, however skilful and able, keep in medical touch and give individual attention to 2,000 cases, or even 1,000? After dealing with the causes and classifications of insanity, Mr. Tuke concluded a very interesting and able address by strongly advocating the need of public education, for great strides as the science of psychology had made, still further progress and more successful results would follow when the public were educated to realise fully that temperance, sobriety, and chastity were the essentials of Christian civilised communities.

### THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The annual dinner of this Society was held at the Trocadero Restaurant last Friday. The chair was taken by the President, Dr. J. F. J. Sykes, and among the company present were Dr. Pye Smith, Dr. Groves, Sir T. Stephenson, Mr. Andrew Clark, Dr. Tatham, Alderman T. Idris, Dr. Whitelegge, C.B., Mr. Courthope-Munro, Dr. Parsons, Dr. Beaton, Mr. T. Cutler, Dr. Shirley Murphy, and Dr. Priestley. Dr. Whitelegge, proposing "The Municipal Authorities," said no public authority could afford to make a mistake in the selection and the support of their medical officers of health; and he was glad to think that municipal authorities were alive to this, and were offering inducements to men of the highest qualifications to engage in public work. Alderman T. Idris (Mayor of St. Pancras) responded. Dr. Pye Smith proposed "The Incorporated Society of Medical Officers of Health." He said the connection of the medical profession with preventive medicine was of the most honourable and

satisfactory kind. Investigation into zymotic diseases had thrown a bright light on methods of preventing disease and of curing and relieving them. He was proud of the public spirit, the unselfish devotion, the courage in opposing vested interests and indifference medical officers of health had displayed. It was due to their persistent efforts through generations that this country had taken the lead in improvements that had made it one of the most healthy in the world. Dr. Sykes, in returning thanks, congratulated the members on the fact that they now numbered 937, and the main body of these were acting medical officers of health. He held it to be essential that in the course of their duties they should make themselves acquainted with some branches of architectural construction, for in these days the tendency was to pack the populations of towns in a manner that was injurious to public health and led to that physical deterioration of which so much was heard. In all classes of society there was this tendency to overcrowd, and the medical profession should join hands with architects and agree among themselves as to the limits of aggregation of population. Mr. Andrew Clark, replying to the toast of "Kindred Societies," proposed by Dr. Groves, said the British Medical Association were endeavouring to forward a Bill in Parliament to get rid of the insecurity of tenure of office of which medical officers complained, and he hoped that during the coming Session that Bill would become law and medical officers would no longer be under liability to removal from office in consequence of doing what they considered to be their public duty.

### France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 16th, 1904.

#### TREATMENT OF LUMBAGO.

In the neuralgic form, the following wafers, according to Dr. Capitan, are very successful:—

Phenacetin, gr. iv ;  
Acetanilide, gr. j ;  
Antipyrin, gr. vj ;  
Salophane, gr. v ;  
Bromide of potassium, gr. iv.

For one wafer ; three daily.

When the patient is of a gouty family, five grains of salicylate of lithine might be added.

In the myalgic forms, pyramidon acts well. However, it must be given in somewhat large doses, from twenty to thirty grains a day. The urine will become red, and give a large deposit of urates. The patient should be watched and the largest dose reached only progressively.

Certain patients derive considerable benefit from the association of antipyrine with salicylate of soda:—

Antipyrine, dr. j ;  
Salicylate of soda, dr. j ;  
Water, oz. ij.

Four or five teaspoonfuls daily.

In every case of lumbago, and in addition to one or other of the above remedies, ten grains of hydrochlorate of quinine should be given morning and evening.

The local treatment should not be neglected. A good liniment is as follows:—

Salicylate of methyl, dr. ij ;  
Tincture of belladonna, dr. ij ;  
Laudanum, dr. ij ;  
Spirits of camphor, oz. iv.

Where the pain is clearly localised, excellent results can be obtained from subcutaneous injections of antipyrine:—

Antipyrine, dr. j ;  
Hydrochlorate of cocaine, grs. v ;  
Water, dr. iij.

Massage, graduated movements, and warm baths terminate the treatment.

TREATMENT OF TINEA TONSURANS BY PROF. GAUCHER.

*Children.*—Cut the hair as close as possible once a week. Every two days wash the head with soap and warm water. Morning and evening, massage the scalp, triturating the diseased spots energetically. After the massage, prolonged friction by means of a tooth-brush with the following liniment:—

Spirits of camphor, oz. iv ;  
Castor oil, dr. j ;  
Tincture of cantharides, dr. j.

*Adults.*—Not necessary to cut the hair, which offers the advantage of masking the spots. The head will be washed once a week with tar soap. Repeated and frequent massage will be done by the patient or someone else in the family. Every evening friction with:—

Eau de Cologne, oz. iss ;  
Spirits of lavender, oz. iss ;  
Tincture of capsicum, dr. j.

The following ointment might be substituted for the above liquid preparations:—

Peruvia<sup>l</sup> balsam, grs. xx ;  
Salicylic acid, grs. xx ;  
Resorcin, grs. xx ;  
Lanoline, oz. iss ;  
Vaseline, oz. iss.

At the same time the patient will be recommended to rub the head every morning with the following slightly stimulant mixture:—

Essence of turpentine, oz. ss ;  
Spirits of camphor, oz. iij ;  
Liquid ammonia, dr. j.

Or in the case of a woman:—

Corrosive sublimate, grs. iv ;  
Glacial acetic acid, min. xx ;  
Resorcin, dr. ss ;  
Hydrate of chloral, dr. j ;  
Tincture of cantharides, dr. j ;  
Tincture of jaborandi, dr. j ;  
Proof spirit, oz. viij ;  
Castor oil, oz. j ;  
Ess. of violets, q.s.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 16th, 1904.

In the *Allgemeine medizinische Zeitblatt-Zeitung*, 17, 1904, Dr. Enis reports a case of

HERPES\_ZOSTER OF A RECURRING, INTERMITTENT OR PERIODIC TYPE.

The patient first came under treatment during a free interval, and complained of paræsthetic symptoms in the left half of the mouth. Examination of the cavity revealed nothing abnormal. The writer prescribed quinine, but without effect ; then nine drops daily of Fowler's solution, again without effect ; later on, pills of ergot and quinine bromide were ordered. In six months 120 pills had been taken. Thirty pills were taken during a period of treatment, then they were stopped for a longer or shorter period, and then begun with again. This time there was no recurrence, and the paræsthetic symptoms disappeared. Further observation of the case might possibly have shown how much of the improvement was due to the treatment and how much to a more favourable season of the year, the disease generally recurring at cold seasons and getting better during the warmer ones ; but the patient was lost sight of through change of residence.

At the Medical Society, Hr. Glucksmann spoke on

**ŒSOPHAGOSCOPY: ITS AIMS, ADVANCES, AND VALUE.**

He thought it was a pity that œsophagoscopy was practised by so few. The reason for this neglect lay in some difficulties that could be easily overcome, and in not being able at the very first to recognise what became visible.

The first to see into the human œsophagus was Kussmaul, who examined the sword swallower in 1868. The first œsophagoscope was constructed by Mikulicz, and several others had effected improvements on it. Œsophagoscopy was not intended to displace the other methods of examining the parts, such as by the sound, but to aid them. By it, carcinoma of the gullet could be diagnosed when sounding failed to discover it, although there had been difficulties of swallowing, and stenosis from caustics had been rendered visible when the sound had passed through it. On the other hand, symptoms had been seen to be due to spasm only when everything had pointed to carcinoma.

It had a therapeutical value when, in a case of stenosis, it permitted the passing of a filiform bougie by visual aid. In all conditions of softening the speaker held the œsophagoscope to be more sparing than the sound, as the latter must pass the contracted part in order to discover it, whilst the former allowed it to be seen from above.

In speaking of the future of œsophagoscopy, he said that since the introduction of the method of operating in rarefied air a new future had been opened to surgery, both of the thorax and of the œsophagus; the œsophagoscope would be called in to facilitate early diagnosis of disease of the œsophagus. He also considered œsophagoscopy to be a step in the direction of gastroscopy. The present methods of gastroscopy were not practicable ones; they were too dangerous, and the stomach resented the introduction of instruments.

Hr. Elsner was of opinion that systematic washing and cleansing of the œsophagus would often render the disagreeable employment of the œsophagoscope unnecessary. By this means he had gradually dilated a very narrow stricture in a boy. In the case of malignant stenosis also the œsophagus could often be kept free for a long time in this way.

Hr. Boas did not think œsophagoscopy of much practical value. The early diagnosis of malignant disease was not much furthered by it, neither would gastroscopy help much in the diagnosis of cancer of the stomach. Kelling, among others, had shown that gastroscopy could diagnose cancer of the stomach early enough for a radical operation to be carried out, but that did not indicate any great advance.

At the Dermatological Society,

**EPITHELIAL CANCER**

was discussed. Hr. Unna recommended the use of the Röntgen rays. Hr. O. Petersen (St. Petersburg) would treat rather expectantly in the early stages before the glands became implicated. He would use continuous soda solutions, the Finsen, Röntgen, or radium treatment, and freezing, but more especially the Finsen treatment. The dosage of radium was still uncertain, and sometimes long-lasting irritations were set up. No cure had resulted from freezing, although improvement had taken place. A case of v. Bergmann's that had been cured was shown by Dr. Schlesinger. He preferred operation: the results of surgery might be ideal if the public could be taught to bring the cases early. So much time, too, was spent in Röntgen treatment that it was too late for operation. The Röntgen rays were less active the deeper they penetrated, and deep action was the chief aim of all cancer treatment. Inoperable cases might be submitted to

Röntgen treatment. If this was energetic enough it certainly had a curative effect.

V. Marschalko had cured an ulcerated tumour the size of an apple in a woman, æt. 77, in four weeks, and in eight months there had been no recurrence. Lesser (Berlin) had quite satisfied himself that rodent ulcer could be cured by Röntgen treatment. Deep carcinomata belonged to the knife and not to Röntgen treatment. Holzkneckt said the future belonged to radium. Kiel was of opinion that if, out of ten cases nine could be cured by Röntgen treatment, and all by surgical procedures, it was the duty of the surgeon to cure all, even if a cicatrix was certain to be left, and the same with rodent ulcer. Petrini had had good results from the combined methods.

**Austria.**

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 16th, 1904.

**ALCOHOLIC TREATMENT OF ERYSIPELAS.**

At the Prague meeting, Walko spoke in high praise of the treatment of erysipelas by means of alcoholic compression in the form of bandages applied to the part affected with wadding or gauze well saturated with a 96 per cent. solution of alcohol. He considers the "Alcoholcellit" prepared by Dieterich an excellent form of applying the alcohol to the part. This preparation is in the form of a jelly, containing 60 per cent. of alcohol, and protected from evaporation by being packed in lead cases which are air-tight. When needed the case is opened and the jelly spread over the affected part with a spatula. Over this is placed a layer of Billroth's "battist," or impermeable cambric, and the whole supported by a bandage. By this means the alcohol is given off slowly and remains long in contact with the part to which it is applied, and continues active for twelve or twenty-four hours. Another firm prepares a gauze with this "Alcoholcellit" under the name of "Duralcolbinden," which is reputed to contain 96 per cent. of alcohol.

Neustadtl said he had obtained excellent results from alcoholic applications in osteo-periostitis and tuberculous tendo-vaginitis. He spoke highly of it in the treatment of tuberculous lymphadenitis and chronic arthritis.

**SPASMUS NUTANS.**

Raudnitz showed the meeting a child to support his theory of nystagmus being caused by confining children to dark rooms. In addition to the nystagmus there was a vibratory shaking of the head. He related how he had kept five dogs four months in a dark kennel, all of which acquired nystagmus and two of them shaking of the head—one of which he produced as interesting.

One month was sufficient in some to produce the nystagmus. These facts, he thought, were potent enough to establish his theory that dark rooms and gloomy neighbourhoods were sufficient to produce spasmus nutans.

Ganghofer was of opinion that there was some truth in Raudnitz' theory, as the greater number of cases he had met with were drawn from dark dwellings, but he had also received them from faultlessly clear, bright homes, where light was abundant.

Fischl could not understand how these experiments of Raudnitz proved anything, far less the theory he endeavoured to propound for the origin of spasmus nutans, because children when very young had the eyes closed, and as they grew older they turned their

eyes to the light no matter how imperfect. In all dwellings there are either doors or windows that admit of a certain amount of light, which would be open for the child to exercise its vision, and therefore in a different position to dogs entirely excluded from light for months. Children in dark rooms instinctively turn their eyes towards any gleam of light, therefore the analogy fails when these experiments are compared.

#### ECHINOCOCCUS HEPATICUS.

Springer showed a child, *æt.* 12, on whom he had performed laparotomy for echinococcus of the liver. By this operation he attached the cystic portion to the wall of the abdomen and after six days had elapsed he opened the cyst and cleared out the sac, which afterwards healed up favourably and left the patient healthy and well.

#### PERITONEAL TUBERCULOSIS.

Thönes gave an analysis of 80 cases which he had treated according to Kummel and Braun's method, operating for tubercle in the peritoneum. He thought the whole question lay between puncture and laparotomy, but the latter, in his opinion, was the most effectual where operation was indicated. If the disease be active, as in phthisis, the operation should be deferred, but where exudation and adhesions are present, laparotomy should be performed, as prolonged internal treatment gives very doubtful results. In the discussion Hippel reported three cases of ileo-cæcal tuberculosis on which he had operated, but all of them died subsequently of anal fistula. He believed this was due to the separation of adhesions in the bowel affected. He is now persuaded that this part of the bowel should have been resected after separating the adhesions.

#### TREATMENT AFTER PURULENT PERITONITIS AND FATTY NECROSIS.

Bertelsmann described the history and dangers of profuse peritonitis followed by collapse due to the empty condition of the heart. To overcome this difficulty he intravenously injects three and a half litres of salt infusion and increases it according to Heinecke's theory to twenty litres in the following days. In a case of fatty necrosis of the peritoneum, this form of treatment was a perfect success.

Oppenheimer discussed the different forms of pulse that required this treatment, and the difference of temperature that existed in peritoneal affections: between the temperature in the axilla and the temperature of the anus. The greater the difference of these two temperatures the more gloomy was the prognosis. Haberer thought that many of these cases with diffuse effusions died not from the relaxation of the heart but toxæmia. In such cases he could not see where salt solutions when injected into the blood could be of much service.

Rehn was of opinion that death was usually accomplished by bacteriæmia and not by toxæmia.

## The Operating Theatres.

### ST. MARK'S HOSPITAL FOR FISTULA.

#### LAPAROTOMY—PECULIAR CONDITION OF THE VISCERA.

—MR. SWINFORD EDWARDS operated on a Russian, *æt.* 57, who had had trouble with his rectum (as it was reported) for fifteen years. On examination of the passage he was found to have a contracted anus, and above this, as far as the finger could reach, the rectum was stenosed, thickened and firmly attached to the surrounding tissues. The sensation communicated to the explorer's finger was as if the pelvis was filled with new growth, but no typical cylindroma could be

detected within the rectum. For this condition Mr. Edwards proposed a left iliac colotomy. The abdominal wall was opened in the left iliac region by splitting the various muscular layers in the direction of their fibres. On opening the abdominal cavity no trace of the sigmoid flexure could be discovered. There were hard masses and nodules to be felt in various portions of the mesentery. Believing that this was a case of malposition of the sigmoid, Mr. Edwards repeated the operation in the right iliac fossa, and here the colon was found, indurated and firmly fixed to the iliac fossa and to the posterior lumbar region. The appendices epiploicæ were likewise indurated and contained separate nodules. The whole of the large intestine to be felt through this incision gave a sensation to the finger as though the parts had been hardened in formalin. Colotomy here seemed impossible, and as there were no acute symptoms of obstruction the operator postponed attempting to open possibly the transverse colon until a later date. Both incisions were closed by suturing first with silk the peritoneum, secondly the muscles, and thirdly the skin and aponeurosis, the last with silkworm-gut. Mr. Edwards said that the pathology of the case was wrapped in obscurity, as against the theory of carcinoma was the long period over which the disease had extended; nor was it an ordinary example of columnar-celled carcinoma of the bowel. Against it being tuberculous was the fact of the density of the induration and the small amount of purulent discharge. The history of the case was somewhat obscured, as the patient was unable to speak a word of English, and only two or three words of German. The operator remarked that he had before come across two cases of misplaced sigmoid colon, that it is to say when this portion of the intestine passes across the abdomen to the right side, lying over the caput coli before turning over the brim of the pelvis. In both of these the sigmoid was opened, colotomy being performed in the right iliac fossa. In the present case, Mr. Edwards was unable to determine whether the large intestine discovered in the right iliac fossa was the sigmoid or the commencement of the large intestine, owing to the parts being so indurated and firmly bound down. It would, he thought, be interesting to know what the subsequent course of the case may be, and what the microscope may show. He suggested that it might be an infiltrating form of carcinoma engrafted on old-standing tuberculous disease, although he had never met with a like case.

OPERATION FOR ANAL TUMOUR.—The same surgeon operated on an old woman, *æt.* about 65, who had had pain and rectal discharge for some months past. There was an external orifice of a fistula in the right posterior quadrant; corresponding with this, about an inch and a half up the bowel, was a large internal orifice surrounded by a considerable mass of what felt like granulation tissue; between the internal and external orifices the induration was considerable, forming a tumour the size of a small hen's egg. Mr. Edwards mentioned that the patient had been admitted for rectal cancer, but he, mistrusting this diagnosis, determined to lay the parts open as when operating for ordinary fistula in order to examine the cut surface of the tumour, and subsequently to proceed as the exigencies of the case seemed to demand. The patient

having been placed on her right side, a probe-pointed director was passed through the fistulous tract, and the probe point brought out at the anus. The intervening tissues were then divided and the cut surface of the tumour exposed to view. It presented a peculiar glistening appearance, and reminded one of grains of boiled sago. The surface of each section measured about one and a half inch by one inch. Mr. Edwards excised both portions of the growth for microscopical examination. After this the wound presented the ordinary appearance of a wound after operation for a deep fistula. Mr. Edwards remarked that in this case the rectal condition gave a sensation to the examining finger as of an ordinary rectal carcinoma, accompanied by a small fistula, but against the malignant theory was, in the first place, the position of the growth, which was situated in the right side of the bowel, just within the external sphincter. Cylindrical-celled epithelioma, he said, usually attacked the bowel somewhat higher up, and when of the nature of squamous-celled epithelioma it usually started about the junction of the skin and mucous membrane, involving first the anal outlet, which the growth under consideration did not; moreover, there was a fistulous track running right through the tumour, which was, to say the least, very uncommon in rectal cancer. Pain, too, was marked by its absence, which, he thought, would not have been the case in rectal carcinoma so low down. From all these considerations Mr. Edwards was inclined to look upon it as some curious form of inflammatory induration, on the exact nature of which he hoped light would be thrown after an examination of the removed growth.

#### ROYAL EAR HOSPITAL.

**OPERATION FOR NASAL OBSTRUCTION.**—Mr. YEARSLEY operated on a woman, *æt.* 45, who complained of complete obstruction on the right side of the nose, with constant colds in the head, severe frontal headache radiating from the root of the nose, and paroxysmal attacks of sneezing. There was loss of smell, occasional deafness, and the patient was quite unable to breathe adequately through the nose. The complete obstruction had lasted since an attack of pneumonia in the winter of 1903, although before that she was often slightly stuffy in the nose, and prone to catch cold. On examination, the septum nasi was seen to be much deviated to the right; the concavity on the left side being occupied by a greatly enlarged middle turbinal body; the right middle turbinal could be partly seen behind the deviated septum and extended downwards into the inferior meatus. Digital examination revealed a large pad of adenoids in the naso-pharynx. The patient having been chloroformed and the nose sprayed with 1 in 1,000 adrenalin solution, the left middle turbinal was removed by cutting through its attachment to the outer wall of the nose with scissors, until a small neck of bone was left. As it was difficult to pass a snare wire round the turbinal, the neck of bone was broken through with Doyen's forceps. The septum was next partly sawn through with a nasal saw and straightened by means of septum forceps, thus enabling the operator to reach the hypertrophied left middle turbinal, which was taken away by means of scissors and snare. Finally, a large pad of adenoids was removed with Kirstein's curette. Mr. Yearsley said that the case illustrated the result of the effect on the nose of the neglect of adenoids. It was quite true that the

symptoms of adenoids often abated at or about puberty, but this was as often due to the enlargement of the post-nasal space as to the disappearance of the adenoids themselves. In this case probably the nasal condition was largely owing to the frequent acute catarrhs induced by the adenoids. Obstruction from enlarged middle turbinals was very common; these bodies frequently become what are practically large bony cysts from chronic inflammatory processes. Owing to the fact that the course taken by the inspired air is a parabola, the highest part of which reaches to about the centre of the middle meatus, any enlargement of the middle turbinal naturally causes obstruction to nasal breathing. The pressure of enlarged middle turbinals upon the septum is a frequent cause of nasal headache; such headaches are very characteristic and often very severe. They commence at the root of the nose and radiate upwards over the frontal region. In such cases removal of the middle turbinals quickly results in the disappearance of this distressing symptom.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 19, 1904.

#### L'ENTENTE CORDIALE—“AU REVOIR.”

THE French “medical caravan” has departed after three days of strenuous labour. Their hours were counted, and each had its allotted task—if the word may also be made to include sundry festivities, public and private, that formed large on the programme. We are fain to confess that our visitors showed themselves indefatigable. If they did not inspect every one of our large general hospitals in detail, if some of them snatched a fearful joy by visiting the Wallace Collection or the National Gallery instead of being conducted round Colney Hatch or the University laboratories, the majority rallied to the bugle-call of duty and fell into the ranks at the appointed hour. While we are too experienced to be rendered vain by the admiration so freely bestowed on our medical and scientific monuments, much of which, no doubt, was mere

politeness, we certainly retain the impression that our visitors took away with them ideas and impressions that may, in their eager hands and fertile brains, influence current views in France. Nothing, perhaps, impressed the more discriminating of our visitors so much as the colossal results obtained in this country by individual and collective effort in the provision of hospital and laboratory accommodation, a contrast to the absolute dependence of similar institutions on the State elsewhere. In commenting on this fact it is in no wise our intention to compare the one method with the other, for each has its peculiar advantages and its inherent drawbacks. Centralisation no doubt makes for economy of administration, but it is destructive of individual initiative; independence of State control confers plasticity upon the organisation, but paves the way to abuses of its own. The difference is seen in the ample floor space allotted to each bed in English hospitals. This is rendered possible by the fact that, being a private institution, conducted in accordance with rule, no patient is accepted in excess of the available accommodation. The French hospital, on the contrary, is a municipal institution, and as such is obliged to admit applicants even though their reception necessitates more or less overcrowding of the wards. Foreigners look with undisguised admiration tinged with envy at the *claires silhouettes des nurses charmantes*, whose presence gives a brightness and suavity to otherwise depressing surroundings. The gaily decorated children's wards, the ample provision of toys and flowers, the general air of comfort and almost happiness that pervades them, touched them to the quick, and the sincerity of their appreciation was apparent. We venture to think that they were not less surprised and pleased—we are speaking of those who only knew the English as painted by French tradition—to find what a genial host is masked by the external austerity of the typical Englishman. Certainly the effort made to entertain our guests rose to the occasion, and nothing, absolutely nothing, was left undone to make their visit both agreeable and instructive. It would, of course, be easy to find fault with the programme, and some would reproach the organisers with having attempted too much, others with having achieved too little, but, in truth, the organisers acted in deference to the maxim that *qui trop embrasse mal étreint*. As it was, the individual members of the band were enabled to choose their intellectual pabulum and direct their steps accordingly. One of the most charming features of the visit was the spontaneity and enthusiasm with which the medical practitioners of the Metropolis threw themselves into the work. Beginning with the tactful visit of Sir William Broadbent and several distinguished colleagues to the station to receive the guests and guide them to their quarters, the same pleasant foresight enveloped them throughout, and each vied with the other in the endeavour to make the reception worthy of the occasion. The King himself took cognisance of the

terminal banquet on Wednesday evening, and with the graceful courtesy that endears him to his people, expressed the interest he took in this incident of the *entente cordiale*. The banquet was literally and figuratively a "huge success," upwards of four hundred convives of the two nationalities being sandwiched at the endless array of tables. The *cuisine* was worthy of the Hotel Cecil, and the post-prandial oratory attained the giddiest heights of French eloquence. A touch of humour was provided by the entertainers speaking French and the guests English. We were peculiarly fortunate in being honoured with the presence of Professor Poirier, whose reputation as an orator is now firmly established north of the Channel. The sober eloquence of Professor Chauffard, M. Lucas-Championnière and Dr. Huchard testified to the qualities of lucidity and harmony that stamp the great French clinical lecturers and confer a charm on their utterances. Receptions of this magnitude cannot, of course, be every-day occurrences. We hope, however, that our French *confrères* will take this one to mean that they are always welcome in our schools, that we entertain feelings of sincere regard and affection for them, and that we look forward to working with them, hand in hand, for the relief of suffering and the greatness of humanity.

#### TWO THOUSAND OPERATIONS FOR APPENDICITIS.

"EVERYTHING," said John Bright, "that can be said on the subject of education has been said hundreds of times over," and the same is almost true of appendicitis. But with that disease continually confronting him, and the question of the right moment of surgical interference still a matter of opinion, the practitioner may derive advantage from the experience of a surgeon like Mr. John B. Murphy, who has two thousand operations for appendicitis to his credit. In the *American Journal of Medical Sciences* for August, Mr. Murphy analyses these cases, their symptoms and course, and gives his opinion on the treatment of the condition in decided words. In dealing with the pathogenesis of appendicitis he mentions having found foreign bodies in 2 per cent. of his cases, a proportion that is higher than is generally supposed to prevail over here, whilst in no less than 38 per cent. faecal concretions were present. Bacteriological examination was diligently pursued, and in order of frequency, he noted *Bacillus coli communis*, *Staphylococcus pyogenes aureus* and *albus*, streptococcus, pneumococcus, *Bacillus tuberculosis* and actinomycosis as the predominating organisms. With regard to the semeiology, Murphy is very emphatic in the importance of pain as the initial symptom of an attack; in the whole of his cases it was the first fact in the illness. Indeed, when vomiting or pyrexia precedes the abdominal pain, he disbelieves the diagnosis, and if the patient's temperature has been raised for a day or two before the onset of pain, he generally suspects typhoid fever. The pain of appen-

dicitis is usually colicky in character, and reaches its maximum intensity in about four hours, when in the majority of cases it begins to subside. Although pain, in his opinion, is invariably the primary symptom, he is equally sure that fever always occurs, sooner or later, in a genuine case, and these two signs, combined with vomiting and tenderness in the right iliac region, and perhaps the whole abdomen, constitute the important features of the onset of an attack. The character of the pulse is of little help, and leucocytosis is of no value beyond showing that absorption of septic products is taking place; indeed, it is not always present, even when pus has formed. After describing the modes by which appendicitis may terminate, either by resolution or by abscess-formation and further infection, Murphy proceeds to describe some of the less common sequelæ that he has met with, two of the most interesting being portal thrombosis and thrombo-phlebitis of the iliac veins with general embolism. Writing from the standpoint of a surgeon, and a very distinguished surgeon too, it is natural that purely medical treatment should find but small favour at Mr. Murphy's hands, and one reads without surprise that every death from appendicitis is due to not calling in a physician early enough, or to the dilatoriness of the physician or surgeon when he is called in. It is all very well for the physician to make an early and accurate diagnosis, but he is not justified in deferring operation because the final results in appendicitis are, on the whole, favourable, whilst the surgeon, on his side, must not run the risk of doing a primary radical operation when an inflammatory condition is present, but rather defer it to a later period. The man who is having more than three or four deaths in a hundred operations is either receiving the patronage of incompetent and procrastinating men, or he is doing too much manipulation in the peritoneal cavity under unfavourable pathological conditions. Such, at least, are Mr. Murphy's views. He then illustrates from his own records the influence that current medical opinion has upon the mortality from the disease. He divides his operations into series of a hundred each and compares the fatality of the various groups. As would have been expected, the highest death-rate, 11 per cent., occurred in the first group, and the lowest, 2 per cent., in the last. With regard to the latter, we may say that, considering that operative cases of all sorts are included in it, and that each of the two deaths were due to causes not directly connected with appendicitis, the result is one reflecting the greatest credit both on the operator and on the practitioners who sought his assistance. He points out, however, that the mortality in his earlier groups fell steadily till 1896, when, at the meeting of the American Medical Association at Atlanta, a great deal of feeling was expressed against frequent abdominal operations, especially those for appendicitis. He traces to this cause the fact that the mortality of his next hundred cases rose to seven, as general

practitioners hesitated before advising operation. This prejudice gradually wore off till 1900, when again a movement in favour of conservatism set in—a state of opinion that found its reflection again in a rise in Murphy's operation fatality: this time to 6 per cent. On this side of the Atlantic there is still a general feeling that the mild cases of catarrhal appendicitis, in which the constitutional symptoms are slight, are best treated by the expectant method, the question of operation being reserved for the period of quiescence, and we do not think that even Mr. Murphy's far-reaching figures disprove the wisdom of this course. We certainly agree with him, however, that it is not safe to allow a patient who has had an attack of appendicitis to wait till another has taken place before considering the question of removal. Mr. Murphy's brilliant results in operations undertaken between attacks, only one death in thirteen hundred cases, should give courage to the most diffident.

### Notes on Current Topics.

#### The Hypodermic Medication in Cancer.

In another part of our present issue readers will find an interesting article by Dr. Shaw-Mackenzie on the treatment of inoperable cancer by hypodermic medication. Although the writer cannot claim any cases of cure, he has nevertheless obtained results of a distinctly encouraging nature, such as relief of pain and shrinkage of tumour-growth. Some granulomata, such of those of syphilis, become definitely absorbed under the influence of drugs introduced into the system. There is nothing on the face of it to show why a similar result may not be obtainable in the case of malignant neoplasms, provided the right drug and the right method of administration be ascertained. Dr. Shaw-Mackenzie has made the pioneer move in the necessary experimentation, and it is to be hoped that other investigators will follow in his footsteps. His full research is not published in the article that appears in the present number of THE MEDICAL PRESS AND CIRCULAR, but those who wish to study the matter in detail will find the opportunity in a pamphlet shortly to be published. Hypodermic medication forms one of many ways in which we may hope one day to solve the problem of how to cure cancer, a subject which still offers to the scientific enthusiast one of the greatest—perhaps the greatest—crowns awaiting the heroes of medicine.

#### Conservatism in Surgery.

THE Huxley Lecture delivered by Sir William MacEwen at the opening of the Winter Session of Charing Cross Hospital has received somewhat more public attention than is usually awarded to such pronouncements. This is in some degree due to the lecturer appearing more or less in the rôle of critic of current surgical practice, but perhaps still more to the fact that his address had to do with

the appendix cæci, an organ which looms very large in the mind of the public. There is perhaps little that is new in Sir William MacEwen's address, but there is much that has not been so well said by any other. He raises the voice of calm reason and common sense against the meddling interference of the tinkering surgeon. He believes that the normal healthy body is a more perfect organism than the maimed creature which would remain after the "improvements" some surgeons advise, even though nothing has been improved away but the apparently useless and functionless. There are many parts of the human anatomy whose function is as yet unknown, but we are far from justified in believing that they are useless. More particularly, Sir William MacEwen applies his argument to the case of the appendix and the cæcum, and though his observations are not complete, he brings forward cogent reasons for the opinion that both structures have very definite purposes to fulfil. He points out that in all herbivorous animals caecal digestion takes place to considerable amount, while in some it is more important than gastric digestion. The secretion of the glands of the cæcum and appendix is affected by the ingestion of food, and the fluid has in all probability a definite digestive value. But apart from any hypothesis as to the functions of the appendix, in the great majority of men it causes no trouble, and there is little justification for the removal of so innocent an organ. This caution against too radical surgery has been given by others before the Huxley Lecturer, but it gains much from his sound common sense as well as from his caustic wit.

#### A Short Way With Lunatics.

THE discussion started some months ago by the publication of a pamphlet recommending the sterilisation of degenerates has received a certain revival by Dr. Fred Smith's paper before the Forensic Section at the Oxford meeting of the British Medical Association. Though much more moderate, both in scope and expression, than the other paper, yet the plans proposed lie much in the same direction, and one cannot but think that Dr. Smith has been influenced by Dr. Rentoul. He takes a very pessimistic view as to the curability of lunacy in general, and he applies this view in particular to the case of the criminal insane. Assuming that the criminal lunatic is unlikely to be cured, why not place him beyond the power of repeating his crime? His execution is not to be regarded in any way as a "punishment," but merely as a safeguard, bearing in mind that he is a useless and probably harmful member of society. In the case of child-murder by mothers, usually a result of puerperal insanity, Dr. Smith thinks a recurrence of the crime can be adequately prevented by the performance of the operation of oöphorectomy, followed by a detention under observation for whatever period may be found necessary in each individual case. In the case of criminals whose insanity is due to alcoholism or

other drug habit, he advises castration, followed by conditional release, as a guard against the multiplication of degenerates. If, however, there should be the slightest lapse from teetotalism, the patient should be returned to the asylum. Excellent as these suggestions might be if we were starting to build up a brand new civilisation, we think they are hardly likely to have much effect on the present condition of European thought.

#### Overlying of Infants.

THOUGH all medical men in practice among the poor are frequently brought into contact with cases of overlain infants, it is doubtful if many are fully aware of the enormous mortality from this cause. In London especially, the number of children killed in this way is so alarming that it can best be realised by stating that the number of deaths from "suffocation in bed" during the past ten years is equal to that from typhoid fever, being little under two thousand each year. When it is remembered that these children are as likely as not to be quite healthy, one can gauge to some extent the loss the nation is sustaining. In most cases, too, it is probable that the deaths are the result of pure accident, though in some, drunkenness in the mother may be the principal cause. It is noticed that the greatest number of deaths from this cause occur on Saturday nights, when there is most probably a greater indulgence in drink than on other evenings of the week. On the other hand, Saturday is the busiest day of the week for most wives of working-men, so that they are inclined, although perfectly sober and temperate, to sleep most soundly on that night. Much good might be done in the way of prevention by the visitation of mothers by tactful female visitors who should advise the use of cots for young infants, and should dissuade from suckling in bed. Instruction on the subject might also be given to the girls in Board Schools, who should certainly receive regular teaching on the care of infants.

#### Treatment of Neuralgia by Injections of Air.

THE use of hypodermic injections of air to produce local anæsthesia is, of course, well known, but various French physicians have in recent times extended this principle to the treatment of obstinate neuralgias. Cordier, of Lyons, experimented on several cases of obstinate sciatic neuralgia, with very considerable success. In more than half the cases treated, one injection, varying in amount from a quarter to half a litre, gave permanent and complete relief, while in only two cases was there failure. Similarly, Mongour and Carles, of Bordeaux, were successful in the treatment of post-herpetic intercostal neuralgia, a complaint most obstinate to other methods of treatment. The mode of procedure is very simple. No apparatus is necessary beyond an ordinary Pravaz or Roux needle, which can be attached to any simple air-pump, such as a common bicycle-inflator, or a rubber bag. If it is thought necessary

to filter the air, a glass tube containing a cotton plug can be interposed between the pump and the needle. Air can be injected until the patient declares that the pain has disappeared. It will take some days for the gas to be absorbed, and until this occurs, the part should be gently stroked each day. Only one caution is necessary—to avoid a vein. The method has much clinical evidence in its favour and deserves a trial in this country.

#### Transplantation of the Urethra.

THE *Annals of Surgery* for last month contain an account of some ingenious attempts by Mr. J. H. Pringle, of the Royal Infirmary, Glasgow, to repair the urethra by substitution. Operations were performed on three different subjects, the urethras of young bullocks being used to replace the damaged or absent urethra in the patients. In one case, that of a boy with hypospadias, seven centimetres of urethra from a bullock were transplanted; but although the graft "took" well it was found impossible to effect union at the juncture of new urethra with the old, and finally the implanted tissue sloughed. The whole of it was excised, and a fresh graft, consisting of nine centimetres of bullock's urethra, was inserted in its place. After some trouble this became soundly incorporated with the living tissues, and the boy finally left the hospital well. He had, however, to pass a bougie to keep the canal patent. Of the other two patients, one was a man of fifty, who had an abscess of the penis that led to gangrene and sloughing of the urethra. After six weeks of supra-pubic and perineal drainage, Mr. Pringle endeavoured to provide him with a new urethra from a bullock; but though the graft grew well, a fistula remained at the junction with the old aperture in the urethra, and several attempts did not succeed in closing it. The third case was that of a young man whose perineal urethra was ruptured by an accident. The transplanted urethra became quickly joined to the surrounding tissues, but a tiny sinus remained in the perinæum. This seemed on the point of healing when, unfortunately, the patient died suddenly after an operation for abscess of the kidney. On the whole, the degree of success obtained by Mr. Pringle may well encourage him to continue using this original method.

#### The Studious Habit.

To few of the sciences does the aphorism that "knowledge is power" apply with so much force as that of medicine. The helplessness of ignorance is never so apparent as when the practitioner is face to face with a great pathological problem, the ins and outs of which are seemingly involved in hopeless obscurity. Some forms of disease will, of course, baffle the most learned at times, yet there are occasions when the veil is lifted as if by magic at the approach of superior wisdom. There is no road to the higher learning save by the narrow and arduous track of ceaseless study. In the busy days which make up the round of active profes-

sional life there remains a minute fraction of time in which the hard-pressed medical man may devote his spare energy—if there be any left—to the duty of keeping in touch with the latest work or, it may be, to the task of investigating for himself some of Nature's pathological secrets. Desultory reading may not appear fruitful, yet if once the necessity of continual self-culture be recognised, systematic habits of study will soon be formed. In this habit has lain the success of many who, but for the formation of the studious habit early in life, would have been condemned to a mediocre existence. The art of "redeeming the time" from this point of view has yet another advantage, which was dwelt on by the Bishop of Oxford in his opening address before the West London Post-Graduate College on October 13th, namely, that a provision for old age is thus laid up. When the body is past work and the easy chair becomes more of a necessity, the mind will perforce turn itself inwards, and happy is he to whom length of years forms no bar to the acquisition of knowledge, and whose study is veritably a mental haven of refuge.

#### Poisoning by Boric Acid.

SOME years ago, at the transition period between vigorous antiseptics and modern asepsis, it was the custom in surgery to make use of boric acid in large quantities. The general belief was that its absorption was quite harmless, and it was applied with the greatest freedom to raw surfaces and operation wounds. Though this custom is now happily nearly obsolete, yet there is still in some quarters a tendency to make use of the dry powder or of a solution in the treatment of abscess cavities, without much regard to the possibilities of free absorption. That such practice is not free from danger is shown by the fact that several deaths have been recorded from boric acid poisoning under exactly these circumstances. Dr. Charles Best, of Chicago, who reports the most recent case,<sup>(a)</sup> and collects particulars of four other fatal cases, points out that all of them resulted either from prolonged irrigation with saturated solution of boric acid, or packing of large cavities with the dry powder. The usual symptoms of severe boric poisoning are profuse vomiting, a papular rash over the face and chest, and a weak, irregular pulse. Post-mortem but little was discovered—some cloudy swelling or fatty degeneration of the hepatic and renal cells, and in one case small subpericardial hæmorrhages.

#### A Massage School.

THE word massage has in the past covered a multitude of sins, from gross quackery to barely-disguised immorality. So distasteful were the abuses accompanying its practice that for many years a number of medical men would have nothing to do either with massage or with masseurs. Even now it cannot be said that the art of massage is entirely in the right hands, or conducted in the

(a) *Journ. of the Amer. Med. Association*, September 17th, 1904.

right way, and we are glad to learn that a school for teaching massage in all its forms is about to be opened under the auspices of the National Hospital for the Paralysed and Epileptic, Queen Square. Practitioners ought to be able to judge of the ability of a masseur or a masseuse to carry out his directions, and the minimum that can be accepted as evidence is the possession of a diploma from some respectable institution framed on right lines. The private teachers who profess to give instruction at present are by no means always persons of recognised status or skill, and their "course" hardly carries conviction of competency with it. The Committee of Queen Square have an admirable opportunity, and may be expected to place the matter in a satisfactory position. It is disappointing to learn that their course of instruction is to last three months only. Considering the high fees that masseurs can earn, and the complexity that the art is acquiring, a year would be none too long to require of their students. When a nurse after three years' training can look to making only two guineas a week, besides her board and lodging, it seems unfair that a masseuse after three months can be in a position to earn a pound or more a day for considerably less work. We hope it is not too late for the Committee to reconsider the matter, especially as Swedish movements are to be included in the curriculum.

#### The Value of Meat Extracts.

THE nitrogenous extractives of muscle are both numerous and complex. The relation of these substances to urea and uric acid was early demonstrated by chemical physiologists, and the identification of carnine acid with anti-peptone, announced by Siegfried and subsequently confirmed by Blake and Fraenkel, was an important contribution to our imperfect knowledge of the question of proteid constitution. From the practical aspect, however, it has been found that creatin, creatinine, xanthine, and allied bodies which are capable of being extracted from fresh meat have comparatively little food value. The use of the word "extract" in this connection is somewhat unfortunate, since to the average individual the word is apt to indicate the concentrated essence of all that is nourishing in meat. All meat extracts are popularly supposed to be very strengthening, and any statement to the contrary is met with incredulity. Even good home-made beef-tea, that mystic concentration of fleshy strength, does not deserve the high opinion which is usually placed upon it, but it may be safely asserted that the best infusion of beef contains very little assimilable proteid, its virtue consisting entirely in the stimulating property possessed by the numerous extractives dissolved therein. The relative merits of meat extracts and beef-tea have been exercising the minds of the Holborn Board of Guardians. One of the medical officers of the Board had declared that "it was impossible to tell what animal it (meat extract) is made from and whether it had died from disease." There is much truth in this

statement, though we are glad to know that some well-known firms really do turn out wholesome products that are above suspicion. On the score of expense, beef-tea is preferable, and as a savoury stimulant there is nothing better in sickness or convalescence, and it is generally most acceptable to the patient.

#### Nurses for Middle-Class Homes.

WE are glad to note that a scheme is on foot for providing people of the middle-class with the services of a nurse in their own homes. As opinions on the subject have been requested, we may say with confidence that there is hardly a practitioner who would not welcome such an arrangement, provided it were properly organised and managed. As matters stand at present the poor in most parts of the country, and in nearly all the large towns, can have the benefit of a nurse's assistance in times of sickness through one or another of our existing philanthropic agencies. No such provision is made for the poorer middle-class. Without advocating that nursing by members of the family—which is certainly a duty, and should be a privilege—ought to be superseded in general, one knows that in many cases additional skilled help is needed in dressing wounds, giving nutrient enemata, and similar manipulations, and this among people of small means who do not wish to avail themselves of public charity. A nurse's fees, especially in long illnesses, are often beyond the resources of the smaller tradesmen and clerks, and with the raising of the standard of sick-nursing that is going on around us, no reduction of fees can be looked for. To place the services of a skilled nurse within the reach of such people would be a worthy and enlightened piece of philanthropy, and we hope that the scheme may be carried through successfully. It is proposed to give the nurses' services gratuitously; this, we think, would be a mistake. The working expenses of the institutions would fall entirely on the funds provided if this were so, and the scope of their operation would be proportionately curtailed. Charging small fees, whose amount was adapted to the patients' means, would not only relieve the income of the committee of a heavy burden, but would be acting on the higher principle of making people help themselves—as far as they are able.

#### The Hygiene of the Elevator.

A CONTEMPORARY has somewhat humorously suggested that a sound article might be written upon the subject of "The Lift, or Elevator, and its Influence on the Physique of Nations." Such a title might not commend itself to the writer of an M.D. thesis, as the number of pathological lesions resulting from the habitual use of the elevator is not great. It may, indeed, be urged by those who love to cavil against the application of hygienic tests to the affairs of daily life that were the lift little better than a death-trap it would hardly signify, seeing that the time spent in one by the average passenger is so short. The

attendant himself, however, would fare ill if such were the case. The view has been put forward, and it is even now held by some conservative folk, that the lift encourages habits of laziness, especially in the young, and that the older and more sensible method of stair-climbing is far more beneficial to the muscular system. Perhaps chlorosis and anæmia were not so common fifty years ago, but there is nothing like a good mount up six or eight flights of stairs to detect the slightest degree of cardiac incompetency accompanying these complaints, which are so frequently met with among our city youths and maidens. An individual suffering from organic disease of the heart would be sorely tried by climbing such heights, whereas by the use of the lift he is enabled to carry on his business without discomfort or increased risk. As a time-saving appliance the elevator has become an absolute necessity, for hurry is the order of the present age. From the surgical standpoint more might be done, perhaps, in the way of providing better safeguards at the entrance of lift-holes, as lamentable accidents not infrequently occur from neglect of such precautions. The ventilation of many elevators is far from perfect, and in busy establishments the lift-man or boy must suffer from the effects of breathing bad air.

#### The Central Midwives' Board and the Rotunda Hospital.

IN our present issue we publish a letter from the Master of the Rotunda Hospital, in which he informs us that the serious difference of opinion, between the Board and the hospital authorities, as to what constituted a properly trained nurse had been at last arranged to the mutual satisfaction of both parties. We are very glad that this is so, and desire to congratulate them on the fact. Common sense must have taught that it was a manifest impossibility to refuse to recognise nurses trained as are those at the Rotunda Hospital, and if the hospital authorities have found it possible to make the alterations suggested by the Board without interfering with the value of the hospital training for either nurses or students, it is well that they should do so. If the present training of the midwife is to be improved it can only be by the careful and intelligent supervision of a Board so instituted as to be suitable for its purpose, and by the loyal assistance of the training centres. If, however, the actions of the Board appear to be governed by prejudice and illogicity, it cannot complain if they are resisted by training centres which did not require reform. While we are referring to this subject, we desire to express our deep regret at the unexpected death of Mr. Heywood Johnstone, M.P., who was largely responsible for the creation of the Board. We have at times been compelled to disagree on different points with his policy on the question of the training of midwives, but that his actions were solely directed to the effecting of a very necessary improvement in the present class of midwife we are sure. It was, however, a pity that he did not allow himself to be

more guided by the advice of the profession which was best calculated to give such advice. Had he done so the piece of legislation with which his name will be always associated would have been more efficacious, and, we fancy, more permanent.

#### The Hygromed.

THE hygromed is a little instrument invented by Dr. Wetherill, of Philadelphia, or rather adapted by him from the spiral hygrometer, with the object of measuring accurately the degree of moisture of the skin in disease. Dr. Wetherill's first step after completing the construction of the instrument was to test its value and authenticity on normal folk, and it was not till he had made a thousand different observations, and ascertained the ranges of variations in health, that he began using the hygromed in disease. It is now ten years since he began work, and he thinks the results he has obtained show that there is a distinct, if limited, scope for his instrument in the examination of the sick. His most practical observations are those made in cases of renal disease, especially in threatening uræmia. He found that when a fall in the quantity of urine was compensated for by an increased transpiration of the skin, the patient's condition was not appreciably changed, but when in renal disease he found a progressive diminution in the dryness of the skin, the danger of uræmia was great. In œdema, the skin was shown to be possessed of less moisture than over parts that were not œdematous, and after hot baths, although perspiration was induced at the time, the moisture of the skin remained below normal for some days afterwards. In exophthalmic goitre cutaneous excretion of water was increased by 10 per cent., and in paralysis the skin was generally drier on the helpless than on the sound side. Many other interesting observations have been recorded of the condition of cutaneous excretion in fever and other conditions, and this clever little instrument may not unlikely soon find its way into the clinical apparatus of the physician.

#### The Therapeutical Society.

THE appearance of the second volume of the *Transactions* of the Therapeutical Society reminds us of the excellent objects of the founders. It bears testimony to the excellence of its work, namely, the desire to advance the knowledge of pharmacology and therapeutics, in the list of papers which have been read and discussed during the year 1903-04. The ground covered by the Society is of the widest, as may be gathered from the range of titles, which include an account of the aconites, the pharmacology of the saponins, the action of bodies in a particulate state, photography in natural colours, inguinal trusses, blood leucocytes, and so on. Variety is certainly to be found here for a wide diversity of therapeutical palates. The present president, Sir W. Thistleton-Dyer, will be succeeded by Sir Lauder Brunton. The popularity of the Society is attested by the rapidly-increasing roll of membership. During the past

year the number has been increased by no less than sixty-two Fellows, twenty-seven of whom are Corresponding Fellows living abroad. Further details of the Society can be obtained from the honorary secretary, Dr. T. E. B. Brown, Willesden Lane, London, N.W.

### Eye Massage.

WITH reference to the comments in our last issue upon "Eye Massage," we are assured by Dr. Ettles, of the Minorities, that he has not been nominated by Mr. Stephen Smith as his "referee," as stated in our article, nor is he in any way "connected with that gentleman or his hospital." This information was founded on statements in at least one London daily newspaper. We are glad, however, to publish this disavowal on the part of Dr. Ettles, and we regret that such misleading information appeared in a public newspaper. Dr. Ettles, moreover "is not an anti-vivisectionist, nor does he at all agree with Mr. Smith's method of correcting defects of vision by manipulation"; at the same time, we must clearly state that no such attitude was hinted at in our remarks.

### PERSONAL.

ACCOMPANIED by Queen Alexandra, the King has graciously consented to lay the foundation-stone of the new King's College Hospital to be erected at Denmark Hill, Camberwell, on a site presented by the Hon. W. D. F. Smith, M.P.

HIS MAJESTY THE KING has graciously consented to give his patronage to the Sanitary Institute, which was founded in 1876, and is carrying on a large work in teaching and examining in hygiene and sanitary science, and maintains in London a permanent museum of sanitary appliances.

LORD KELVIN will present the prizes at the St. George's Hospital Annual Distribution, on October 28th next.

SIR WILLIAM COLLINS, M.D., has been re-elected President of the Medico-Legal Society for the coming year.

SIR PATRICK MANSON, K.C.M.G., M.D., will deliver an address on the significance of fever in patients from warm climates at the autumn meeting of the West Somerset Association Branch, to be held at Taunton on November 4th.

SIR WILLIAM MULOCK recently embodied an amendment to the Post Office Act in the Canadian Parliament with the view of prohibiting the passage of quack advertisements through the post.

PROFESSOR W. R. SMITH is announced as Conservative and Unionist candidate for the representation in Parliament of the Glasgow and Aberdeen Universities. As the previously selected candidate, Sir Henry Craik, is still before the constituency, the path of the Liberal party seems likely to be somewhat cleared of obstacles if Dr. Smith persists in his candidature.

PROFESSOR KOCH, on his way to Africa, is at present paying a visit to Paris, where he has several times visited the Pasteur Institute and the Academy of Medicine.

At the Inauguration Ceremony of the University of Leeds the honorary degree of Doctor of Science

was conferred upon a number of distinguished scientific men, amongst whom were Sir Arthur Rucker, Sir T. E. Thorpe, the well-known chemist, and Professor L. C. Miall, the biologist.

THE honorary D.Sc. was conferred upon the following physicians and surgeons:—Sir William Broadbent, Mr. C. G. Wheelhouse, Mr. Jonathan Hutchinson, F.R.S., Mr. T. Pridgin Teale, Dr. John Hughlings Jackson, Mr. A. W. Mayo Robson, and Dr. Tempest Anderson, the ophthalmologist and authority on volcanoes.

DR. H. LESLIE ROBERTS has been appointed to the newly-created post of lecturer on dermatology in the University of Liverpool.

MR. C. CARTER BRAINE will take the chair at the annual dinner of the Society of Anaesthetists, to be held on October 21st, at the Hôtel Métropole, London.

MR. C. ST. AUBYN FARRER, Westbourne Park Road, London, W., will be pleased to hear from any medical men wishing to take part in the forthcoming inauguration of the Association of Medical Diplomates of Scotland.

SIR LAUDER BRUNTON, M.D., F.R.S., has just returned to London after his visit to the United States.

MR. JAMES CRAIG, F.R.C.P.I., Physician to the Meath Hospital, Dublin, and Registrar to the Royal College of Physicians, has been elected General Secretary of the Royal Academy of Medicine in Ireland.

It has been extensively rumoured during the past week that the post of President of the Queen's College, Cork, is to be filled by the appointment of Professor Reginald Windle, Professor of Anatomy in the University of Birmingham. It is probable that by the time we go to press this rumour will have been confirmed.

SURGEON-GENERAL EVATT has arrived in Ireland at the request of the Irish Medical Association. We understand that he proposes to hold a series of meetings through the country at which the present condition of the Poor-law Medical Service will be discussed, and that he has also been asked to assist at the reorganization of the Association itself.

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND.

PARLIAMENTARY REPRESENTATION OF GLASGOW AND ABERDEEN UNIVERSITIES.—The Universities of Glasgow and Aberdeen Conservative and Liberal Unionist Association have recently issued a circular recommending Professor W. R. Smith, M.D. Aberd., D.Sc. Ed., barrister-at-law and J.P. for the County of London, as a candidate for the vacancy which will arise at the next general election owing to the retirement of the Right Hon. J. A. Campbell, M.P. In making the selection the Association were influenced by the recommendations of a Committee, to whom they referred the subject—that the candidate should be a medical man, and that, if possible, he should be an Aberdeen graduate. The medical Faculties of the Universities have never hitherto been directly represented in Parliament, and for the past twenty-four years the member has been connected with the University of Glasgow, although a general understanding exists that nomination should be exercised alternately in favour of a graduate of each University. Apart from all questions of politics, we cannot but desire that the medical representatives in Parliament should be added to, especially when, as in the case of Professor Smith, the candidate is one who would so materially add weight to the votes of his professional brethren in St. Stephens.

Professor Smith has for the past fifteen years been Professor of Forensic Medicine and Director of the Laboratories of State Medicine at King's College. He has been medical officer of the London School Board, and medical officer of health for Woolwich. He has taken a prominent part in all matters concerning public health, has filled the office of President of the Royal Institute of Public Health, and is a member of the Metropolitan Asylums Board. It is unfortunate, however, that his candidature cannot be supported by the official party associations of the Universities, who have already a candidate in the field. From a communication which has appeared in the daily press it appears that the official associations of the two Universities met in the spring of this year and unanimously resolved to recommend to the constituency as its next member Sir Henry Craik, who is about to vacate the office of secretary to the Scottish Education Department. Under the circumstances the rivalry between the candidates is not one of politics, since both are Unionists, but consists in the fact that the original official candidate is apparently to be opposed by a non-official medical candidate. Both parties assert that they have considerable prospect of success. The outcome of the affair will be watched with interest; we note in the last clause of the London Association's circular that Professor Smith "has not at present signified his assent to become a candidate, and prefers not to do so until the general wishes of the graduates are known." It seems that very little, if anything, of Dr. Smith's candidature was known in Scotland until the circular was actually issued.

**CALEDONIAN MEDICAL SOCIETY.**—The greater part of the current number of the *Caledonian Medical Journal* is occupied by an account of the proceedings in connection with the annual meeting. The society now numbers 230 members, of whom 90 reside in Scotland, 107 in England, and 18 in "other" foreign countries, chiefly South Africa. The following office-bearers for the year 1905 were elected:—President, W. Stewart, M.D.; Vice-President, W. A. Mackintosh, M.D.; Secretary and Treasurer, S. R. Macphail, M.D.; Council, David Blair, M.D. George Gilson, M.D., John Keay, M.D., W. Murray Lester, M.D., Alex. McDonald, M.D., and Professor W. Japp-Sinclair. The chief feature of the meeting was an address by the retiring president, Dr. George Mackay, on "Ancient Gaelic Medical Manuscripts," in which it was suggested that the Caledonian Medical Society should consider it their duty to share in transcribing, translating and rendering intelligible to their contemporaries these interesting documents. The proceedings concluded by the annual dinner, held in the Caledonian Station Hotel.

**MEDICAL PRESENTATION.**—Dr. Andrew Graham, Currie, a well-known Midlothian practitioner, on the occasion of his semi-jubilee of practice in the district, was entertained at a dinner in the Craig Memorial Hall, Currie, on the 14th inst. Sir James Gilson Craig, who presided, presented Dr. Graham with an illuminated address, and a cheque for £100, and Mrs. Graham with a silver tea service and salver in the name of his numerous patients and friends in the district.

#### BELFAST.

**THE BELFAST GUARDIANS.**—The members of the Belfast Board of Guardians do not seem to be as gallant as is expected of Irishmen, for at their meeting last week, when they proceeded to appoint a resident medical officer, they rejected three lady applicants and appointed the one man who applied! The successful applicant, Dr. Patton, had been doing temporary duty in the workhouse, and came into the board-room in the usual white jacket, to which one of the guardians promptly took exception, saying the candidate should have appeared before them properly dressed. The chairman explained that this was the usual professional costume, but the worthy grocer refused to be comforted, and maintained that the doctor was not sufficiently respectful to his employers.

**THE NEW SANATORIUM.**—The Local Government

Board having sanctioned the purchase of the Abbey at Whitehouse as a Workhouse Sanatorium for Consumptives, arrangements are being made for the use of the same. It is proposed to accommodate twenty-five patients, as well as the administrative staff, in the house, and twenty-five patients more in new buildings in the grounds. It is also proposed to appoint a resident medical officer at £120 per annum, with rations and apartments, and a visiting medical officer to visit every day, at £150 per annum. Dr. Ritchie, a medical member of the board, objected to the proposed salaries as too high, but did not say at what figure he would rate the services of his professional brethren.

**THE DANGER OF NITRIC ACID.**—A case was heard at Lurgan Quarter Sessions last week in which a minor, by his mother, sued for £20 damages against a local chemist who he had consulted about warts on his hand. The chemist gave a small bottle of nitric acid, labelled "Poison," and told him to touch the head of the wart with the cork of the bottle. He did so, and suffered so much that the finger had to be amputated in the Lurgan Infirmary. His Honour held that the fact that the boy had been told to apply the acid with the end of the cork was sufficient warning to the mother to exercise due care in its use. He was sorry for the boy's sake that he was compelled to dismiss the case.

**NOTIFICATION OF INFECTIOUS DISEASES—TEST CASE.**—A case of some interest to medical men was heard at Newtownards Petty Sessions last week, when the Urban Council sued the mother of a child who had suffered from scarlatina for not notifying the case, and also sued Dr. Parke, the medical man in charge of the case, for not notifying it sufficiently promptly. The mother of the child was fined 10s. and 1s. 6d. costs, and the case against Dr. Parke was then taken. It appeared that the child was removed to hospital on Sunday, and that Dr. Parke sent in his note on Monday evening. The Act says that the case is to be notified "forthwith," and on the ground of his delay Dr. Parke was fined a similar amount to the mother of the child.

#### KING'S COLLEGE HOSPITAL AND ANTI-VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sorry to find that a passage in the Address which I delivered at King's College on October 4th has given rise to some misapprehension, which I will ask you kindly to give me the opportunity of correcting. The passage in question is as follows:—"The laboratories of experimental pathology and also of neuropathology cannot conveniently be transferred to the new hospital, for the council and hospital staff are agreed that original researches in these subjects which may involve experiments on living animals shall find no place within its walls." In the scheme described in the address a strong dividing line is drawn between the "early" and the "advanced" studies. The former will be carried on at King's College in the Strand, the latter at the new hospital at Camberwell. But the subjects referred to in the passage clearly belong to "advanced" studies, and, therefore, might naturally be expected, under the scheme, to form part of the student's education at the hospital. They cannot, however, as I have said, be conveniently transferred to the hospital for the reason assigned. It appeared desirable, therefore, to call attention to what is an important exception to the general rule.

These studies have always been carried on in the laboratories at King's College, never in King's College Hospital, and there will be no change therefore in the existing arrangement. As regards experiments on living animals, such as inoculations, for diagnostic purposes, these have never been performed in King's College Hospital, but always in the appropriate laboratories at King's College. In view, however, of the

greatly increased distance between the hospital and King's College in the future it will obviously be necessary that provision should be made at the hospital for investigations of this nature.

There was not the slightest intention, in the passage to which you take exception, to imply any antagonism on the part of the council and medical staff to the employment of experiments on living animals.

I am, Sir, yours truly,

THOMAS BUZZARD.

Grosvenor Street, October 14th, 1904.

[Inoculations for diagnostic purposes, it is clear from the foregoing explanation, will in future be made at King's College Hospital. They are technically "vivisections," and therefore traverse the general inference from the passage quoted from the address.—ED.]

#### THE CENTRAL MIDWIVES BOARD.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In view of the attention that has been lately drawn to the proceedings of the Central Midwives' Board in connection with the status of Irish trained midwives to practise their profession in England, I take the opportunity through your columns to announce that the points at issue between this Board and the Governors of the Rotunda-Hospital have been amicably arranged.

The Central Midwives' Board have formally intimated their intention to ask the Privy Council to modify their rules so as to permit our hospital to be placed on the register of Institutions whose certificates will be accepted.

Our thanks are particularly due to you, Sir, for your able and untiring advocacy of the claims of Irish trained nurses to equal recognition with those educated in other parts of the United Kingdom.

I am, Sir, yours truly,

E. HASTINGS TWEEDY,

Master, Rotunda Hospital.

Dublin, Oct. 12th, 1904.

#### ALCOHOLISM AND INSANITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We may, I think, congratulate ourselves on the fact that Professor Clouston has taken up this matter of the relation of alcohol to insanity. The scientific aspects of the matter are still imperfectly understood; indeed, they amount to little more than well-informed and reasonable speculation. The advent of any candid, clear-headed, and specially equipped investigator is, therefore, to be hailed with delight by all interested in this great social problem, whose vital bearing it would be indeed hard to over-estimate. Speaking as a medical man, it has always seemed to me the main difficulty in approaching the question is that of separating cause from effect. Does the drunkard make the lunatic or the lunatic the drunkard? In other words, is the alcoholism causative or symptomatic? In any case, the evil of alcohol, as pointed out by Dr. Clouston, is preventable, and be the margin of this form of madness great or small, it should be done away with among a civilised and self-respecting community. But, then, so also should alcoholic cirrhosis of the liver and delirium tremens. The quality of the alcoholic drink is another factor of prime importance; bad liquor spells ruin to body and to mind. The way in which the humblest citizen may help his countrymen to rise to better things is by voting in favour of wise restrictive legislation upon the production and the distribution of alcoholic drink both as regards quality and quantity. It is to be hoped that the matter thus ably opened up by Dr. Clouston will be widely discussed by competent critics.

I am, Sir, yours truly,

DAVID WALSH.

Hanover Street, London, W.  
October 17th, 1904.

#### Obituary.

LIEUT.-COLONEL GEORGE RYAN, R.A.M.C.

THE death is announced at Ryde, Isle of Wight, of Lieutenant-Colonel George Ryan, late R.A.M.C., at the age of 59. He entered the Service in March, 1868, as Assistant-Surgeon, becoming Surgeon in 1873, Surgeon-Major in 1881, and Surgeon-Lieutenant-Colonel in 1889, when he retired. Lieutenant-Colonel Ryan served in the Zulu war of 1879. He took the L.R.C.S. and L.R.C.P. Edinburgh in 1867.

WILLIAM CHATTAWAY, F.I.C., F.C.S.

MR. WILLIAM CHATTAWAY, the superintendent of the Apothecaries' Hall, died on the 7th inst. at the age of 43, after undergoing an operation for appendicitis. He was a Fellow of the Institute of Chemistry and the Chemical Society, an ex-Vice-president of the Society of Public Analysts, and at the time of his death filled the office of Public Analyst for Hammersmith and Colchester.

EDWARD WILLIAM ORTON, L.R.C.P.Ed.,  
M.R.C.S.Eng.

AT Bedworth, on the 7th inst., the death occurred of Mr. Edward W. Orton, one of the best-known medical practitioners in North-east Warwickshire. He was the last of the old school of sporting doctors of that part of Warwickshire, and to within a few years ago was a regular follower of the Atherstone foxhounds. Deceased was 63 years old, and had held many public appointments, including that of Medical Officer and Public Vaccinator of the Bedworth District. He was educated medically at Queen's College, Birmingham, and in 1870 took the London M.R.C.S., and the Edinburgh L.R.C.P. and L.M.

JAMES WALLACE, M.A., M.D.Glasg., L.R.C.S.Ed.

DR. JAMES WALLACE, Medical Officer of Health for Greenock, was found dead in bed on the morning of the 10th inst. He retired to rest on Sunday night apparently in his usual health. He was in his eightieth year, and was one of the oldest physicians in Scotland. Deceased had held numerous appointments, including that of Physician to Greenock Infirmary and Examiner in Surgery and Clinical Surgery in Glasgow University. He took the Glasgow degree of M.D. in 1850, L.R.C.S. Edin. and F.F.P.S.Glasg. in 1851.

#### Literature.

REPORT OF THE PRISONS BOARD, IRELAND. (a)

OF 19 preliminary pages of this blue-wrapped volume, the "Report" proper occupies but 13. An Appendix, of matters manifold, constitutes the bulk of the contents, as it runs to 159 pages. Such a document as the present possess, of course, an interest for civilised humanity in general, and for the theorising philanthropist in particular; but most particularly of all for the most practical of all living philanthropists, the truly representative medical man who is devoted to the practice of his profession. The present report presents but comparatively trifling variations in the statistics of committals from those of the last preceding. "The number of criminal prisoners committed to the local prisons during the year 1903 was 32,294, and the daily average number in custody 2,296. These figures show a decrease of 101 and 30 respectively, compared with the corresponding figures for the previous year. In addition to the numbers above, 74 prisoners were committed to local prisons during 1903, under civil process, being an increase of 12 compared with the previous year. The number committed to bridewells during the year was 455, being 227 less than during the previous year." The compilers of the present report "concur in the conviction expressed by the Prison

(a) "Twenty-sixth Report of the General Prisons Board, Ireland" 1903-04; With an Appendix. Dublin: Alex. Thom and Co., Limited.—1904.

Commissioners for Scotland in their last Annual Report as follows: 'It is our conviction that short sentences of imprisonment are not only useless for reformation, but actually harmful to the prisoner.' As a large proportion of such punishments are inflicted on parties convicted of the time-honoured practice of being "drunk and disorderly," it is very easy to comprehend the accuracy of this view. And as the bulk of such cases are always supplied by the dregs of the population of the cities and larger towns, they do not very well represent any portion of the general morality of a nation. Cities are always cities, and always will be so long as human nature and its unsatisfactory craving remain the same. Turning to the table which sets forth the number of sentences to penal servitude passed in Ireland at various periods, the view is much more encouraging. The first year included in this table is 1855, the last is 1903. The number convicted in the former year was 518, in the latter 79. The decline was not uniform; after having dropped to 68 in the year 1897, it rose to 91 in 1898; in 1899 the number was 89; in 1900 it fell to 59; another wave carried it up to 75 in 1901; after which it dropped in 1902 to 57, the lowest record of all. As Ireland has for the past quarter of a century been gradually passing through the throes of a revolution, the records of brutal and otherwise atrocious crime perpetrated in the country during that period are decidedly encouraging. Even in the worst years of the "agitation," when agrarian outrages were at their highest record level, the proportion of murders to the total population of Ireland was one of the lowest of any community in the world. The reins of Government have now been transferred to the people; we sincerely hope that one of the most conspicuous results of the change will be a progressive diminution of crime. The philosophy of history teaches that in all countries and in all ages, the inevitable result of the ruthless administration of draconic laws has been an increase of the worst forms of crime. When the philosophic physician and enthusiastic naturalist, Andreas Sparrmann, M.D., visited South Africa (1772-1776), his observations on the relationships of the Dutch Colonists and their Hottentot slaves, and Hottentot and Bosjesman neighbours inclined him to entertain the surmise that the earliest practice of cannibalism among the savage races of any country was a result of brutal oppression. Breaking on the wheel and subsequent impalement was a frequent termination of the life of a recalcitrant slave. The impaled and mangled convict often lived for several days. The Cape passed into the hands of the English, and such forms of capital punishment were abolished. When John Barrow visited the colony a quarter of a century later, he found that the executions had become so few after the amelioration of the law that one of the two hangmen had, in a state of want and despair, officiated on himself!

### Medical News.

#### The Royal City of Dublin Hospital.

At a meeting of the Directors of this hospital, held on Thursday last, the vacancy in the visiting staff due to the death of Dr. J. L. Lane, Gynæcologist to the hospital, was announced, and it was decided to hold the election about the middle of November. We understand that already some half-a-dozen candidates are in the field.

#### The Medico-Legal Society.

The third annual general meeting was held on October 11th at the rooms of the Society, 22, Albermarle Street, W., when the following officers were appointed for the ensuing session:—President, Sir Wm. Collins, F.R.C.S. Vice-Presidents, Dr. Matthew Hay, Dr. Bostock Hill, Mr. C. H. Hopwood, K.C., Sir Thomas Stevenson, M.D., and Mr. Justice Walton. Treasurer, Mr. John Troutbeck, M.A. Council, Dr. Danford Thomas, Dr. J. G. Carson, Dr. Harvey Littlejohn, Dr. Wm. McCallin, Earl Russell, Mr. Walter Schröder, Dr. Clave Shaw, Dr. F. J. Smith, and Dr. Wynn Westcott. Secretaries, Mr. R. Henslowe Wellington and Dr. Stanley B. Atkinson.

#### Royal Academy of Medicine.

THE annual meeting of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on Friday last, when the following officers for the ensuing year were elected:—President, Sir Thornley Stoker; General Secretary, James Craig; Secretary for Foreign Correspondence, Sir J. W. Moore.

*Medical Section.*—President, the President, R.C.P.; J. B. Coleman, W. R. Dawson, H. C. Drury, T. P. Kirkpatrick, G. Peacocke, F. C. Purser, R. Travers Smith, W. Langford Symes, W. J. Thompson, W. A. Winter.

*Surgical Section.*—President, the President, R.C.S.; Alexander Blayney, T. E. Gordon, John Lentaigne, R. B. M'Causland, R. C. B. Maunsell, Sir Lambert Ormsby, John B. Story, E. H. Taylor, W. Taylor.

*Obstetrical Section.*—President, A. J. Smith; Paul Carton, R. H. Fleming, R. A. Flynn, J. H. Glenn, A. J. Horne, H. Jellet, F. W. Kidd, W. C. Neville, R. D. Purefoy, T. H. Wilson.

*Pathological Section.*—President, H. C. Earl; A. H. Benson, H. C. Mooney, T. G. Moorhead, A. C. O'Sullivan, A. R. Parsons, F. C. Purser, J. A. Scott, John B. Story, A. H. White.

*Section of Anatomy and Physiology.*—President, Edward Taylor, A. Birmingham, D. J. Coffey, A. F. Dixon, A. Fraser, J. Alfred Scott.

*Section of State Medicine.*—President, Sir J. Moore; W. R. Dawson, F. C. Martley, J. M. Redmond, W. A. Winter.

Professor Fuchs, of Vienna was elected an Honorary Fellow. A resolution of thanks to the retiring General Secretary was unanimously adopted.

#### Glasgow Eastern Medical Society.

THE opening meeting of the session was held on October 5th, when the President, Dr. James Dunlop, delivered an address on the Sanatorial Treatment of Consumption. The following were elected office bearers for the session 1904-05:—President, Dr. James Dunlop. Vice-President, Dr. Miller Semple. Secretary, Dr. P. S. Buchanan. Treasurer, Dr. J. Wilson Mathie. Reporting Secretary, Dr. Hugh H. Borland. Sealkeeper, Dr. Thomas Russell. Council, Dr. Joseph Green, Dr. John A. C. Macewen, Dr. A. Laurie Watson, Dr. John Anderson, Dr. W. Adam Burns, and Dr. John W. Finlay. Auditors, Dr. Robert Wilson and Dr. T. C. Barras.

#### Meath Hospital.

THE Session at the Meath Hospital was opened on Tuesday by Mr. Conway Dwyer, who delivered an interesting address on "The Evolution of Modern Surgery," which we hope to publish in our next number. Sir Francis Cruise, M.D., occupied the chair. On the motion of Sir Thomas Myles, seconded by Sir Lambert Ormsby, a vote of thanks was passed to Mr. Dwyer. A similar vote to the Chairman was passed, on the motion of Sir John Moore.

#### Glasgow Southern Medical Society.

THE opening meeting of the tenth session of this Society was held on October 6th, and the following office-bearers were elected for the ensuing year:—Honorary President, Mr. H. E. Clark. President, Dr. J. Hamilton. Vice-Presidents, Professor R. Stockman and Dr. T. K. Munro. Treasurer, Dr. T. Forrest. Secretary, Dr. J. Weir. Editorial Secretary, Dr. R. W. Forrest. Sealkeeper, Dr. A. Wauchope. Extra members of Council, Dr. John Stewart, Dr. D. Macgilvray, and Dr. R. J. Carroll. Court Medical, Mr. T. Richmond Dr. J. C. A. Smith, Dr. G. H. Edington, Dr. A. Roxburgh, and Dr. John Brown. Governor of Victoria Infirmary, Dr. C. E. Robertson.

#### St. Vincent's Hospital, Dublin.

DR. M. McHUGH delivered the introductory address at the opening of the winter session at St. Vincent's Hospital, Dublin, on Wednesday, in which he dealt with the position and demands of the dispensary doctors who, he said, numbered, roughly, 50 per cent. of the profession in Ireland. His address is published in another column. Mr. O'Neill, Chairman of the Dublin District Council, in moving a vote of thanks to Dr. McHugh, said that whenever the local bodies made an

effort to do even a minor justice to the unfortunate dispensary doctors, the Local Government Board erected every barrier and obstacle that they could possibly conceive in order to prevent these remedial measures being carried out. His advice to the profession was to organise and agitate. Dr. Cox seconded. The Chairman (Mr. Waldron, M.P.) thought the demands reasonable. Surgeon-General Evatt, C.B., was moved to the second chair, and a vote of thanks was passed to Mr. Waldron on the motion of Mr. McArdle, seconded by Mr. Tobin, which was passed unanimously.

#### Dublin Hospital Appointments.

DR. DAVID GRAY, who filled the position of House Surgeon for some time past at Jervis Street Hospital, has been appointed House Surgeon at the Westmoreland Lock Hospital. Dr. L. J. Farrell succeeds Dr. Gray as principal house surgeon, and Dr. W. B. Loughman is appointed to fill the vacancy on the Jervis Street Hospital staff.

#### South-West London Medical Society.

THE annual dinner of this Society was held at the Café Monaco, Piccadilly Circus, London, W., on October 7th, when about 50 members and guests were present. The chair was taken by Mr. E. F. White, the President. The toast of "The Society" was proposed by Dr. W. H. Allchin, and responded to by the President. Surgeon-Major Mark Robinson proposed "Our Kindred Societies and Visitors," to which Sir R. Douglas Powell and Mr. F. F. Burghard replied.

#### Society for the Relief of Widows and Orphans of Medical Men.

At the quarterly Court of Directors, held on Wednesday last, October 12th, at 11, Chandos Street, London, W., Dr. Blandford, treasurer, in the Chair, three new members were elected and the death of a member reported. There were no fresh applications for grants. The death of a widow was announced, who had received £957 since January, 1879. Applications for renewal of grants were received from 52 widows, 13 orphans, and 3 orphans on the Copeland Fund, and it was resolved that £1,293 be distributed at the next court subject to the report of the visitors. On the motion of the acting treasurer it was decided to give at Christmas £10 to each of the 52 widows, £3 to each of the 13 orphans, and £5 to each of the 3 orphans on the Copeland Fund—in all, £574. The expenses of the quarter were £60 14s. 6d.

#### International Congress of Surgeons.

PRESIDENT LOUBET opened the seventeenth International Congress of Surgeons in Paris on Monday last, and yesterday Dr. Doyen, the free lance of the profession in that city, was announced to read a highly contentious paper on "The New Treatments of Cancer," of which we shall probably hear more anon.

#### PASS LISTS.

##### University of Durham—Faculty of Medicine.

The following degrees in Medicine and Surgery were conferred on October 1st:—

*Doctor in Medicine.*—John S. Hall, M.B., B.S.Dur., John R. Halliday, M.B.Dur., Frank Jeffree, M.B.Dur., Alfred Parkin, M.B., B.S.Dur., F.R.C.S., Godfrey de Bec Turtle, M.B., B.S.Dur., and William H. Wigham, M.B.Dur.

*Doctor in Medicine for Practitioners.*—Ernest D. Bower, M.R.C.S., F.R.C.S.E., Beaumont H. Comerford, M.R.C.S., L.R.C.P., Philip H. Dunn, M.R.C.S., L.R.C.P., John K. Frost, M.R.C.S., L.S.A., D.P.H., William V. Furlong, L.R.C.S.I., L.R.C.P.E., Frank K. Holman, M.R.C.S., L.R.C.P., Richard M. Hugo, L.R.C.P.I., L.M., F.R.C.S.I., Thomas S. Jones, M.R.C.S., L.R.C.P., F. St. John Kemm, L.R.C.P. and S., L.S.A., Arthur C. A. Lovegrove, L.S.A., Thomas H. Mitchell, L.R.C.P. and S.E., Herbert E. Rowell, M.R.C.S., L.R.C.P., George J. Smith, L.R.C.P. and S., L.M., James B. Wall, L.R.C.P. and S., George R. Williams, M.R.C.S., L.R.C.P.

*Master in Surgery (M.S.).*—Lachlan G. Fraser, M.D., B.S.Dur., and Alfred H. Proctor, M.B., B.S.Dur.

*Bachelor in Medicine (M.B.).*—John A. Bell, Henry M. Braithwaite, Arthur Budd, Llewelyn A. H. Bulkeley,

Lewis A. Clutterbuck, L.R.C.P. and S.Ed., L.R.C.P.I., William E. Falconar, Harold E. Featherstone, Margaret D. French, Norman H. Hume, Thomas C. Hunter, Sophia B. Jackson, William W. Jones, George E. Lloyd, Colin F. F. McDowall, Stanley Robson, William T. Sewell, Arthur L. Sheppard, William E. Stevenson, William L. Tindle, Janet A. Vaughan, Samuel G. Webb.

*Bachelor in Surgery (B.S.).*—John A. Bell, Henry M. Braithwaite, Arthur Budd, Llewelyn A. H. Bulkeley, Lewis A. Clutterbuck, L.R.C.P. and S.Ed., L.R.C.P.I., Harold E. Featherstone, Margaret D. French, Norman H. Hume, Thomas C. Hunter, Sophia B. Jackson, William W. Jones, George E. Lloyd, Colin F. F. McDowall, Stanley Robson, William T. Sewell, Arthur L. Sheppard, William E. Stevenson, Janet A. Vaughan, Samuel G. Webb.

*Diploma in Public Health (D.P.H.).*—Charles R. Stewart, M.B., B.S.Dur., and John Stokes, M.D., B.S., L.S.Sc.Dur., M.R.C.S.

#### Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE following gentlemen, having passed the requisite examinations of the Conjoint Board, were admitted Diplomates in Public Health:—James Allison, M.B., C.M., Kershaw Dinshah Khambatta, L.M. and S., L.R.C.P. and S.E., Alfred Robert Maclurkin, M.B., Ch.B., Daniel Mackinnon, M.B., Ch.B., Richard Staward, F.R.C.S.E., Alexander Mouat, M.B., Ch.B., Lambert Kenneth Rodriguez, L.R.C.P. and S.E., Herbert Francis Lechmere Taylor, M.B., C.M., Herbert De Carle Woodcock, M.R.C.S. Eng., L.R.C.P. Lond., and David Dryburgh Gold, M.B., C.M.

At the same Sederunt, Messrs. James Alexander Raeburn, M.B., Ch.B., and Mowbray Taylor, M.B., C.M., passed the first examination in Public Health; and Mr. Robert Dods Brown, M.B., Ch.B., passed the second examination in Public Health.

#### Society of Apothecaries of London.

At the primary examination the following candidates passed in the subjects indicated:—

*Part II.*—Anatomy: L. W. Bradshaw, Leeds; A. C. Dickson, Guy's Hospital; J. W. Harrison, St. Mary's Hospital; L. R. Nézet, Edinburgh; H. N. Ritchie, Sheffield; and N. C. Wallis, London Hospital. Physiology: R. Beesley, Manchester; L. W. Bradshaw and T. P. Braim, Leeds; J. W. Harrison, St. Mary's Hospital; W. P. Pinder, Leeds; H. N. Ritchie, Sheffield; and N. C. Wallis, London Hospital.

#### The Royal University of Ireland.

*The Third Examination in Medicine—Autumn, 1904.*—The examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—

*Upper Pass.*—James J. A. Gannon, Charles R. Harvey\*, Robert J. Ledlie, Victor J. McAllister, Patrick T. McArdle\*, Charles B. Pearson\*, Percy B. Ridge, Charles H. G. Ross, James Shaw\*, Thomas Tobin\*, James Warnock\*, M.A. Those marked with an \* may present themselves for the further examination for honours.

*Pass.*—Harry L. Bristow, Francis X. J. Callaghan, John A. Clarke, John Dempsey, John Dunlop, Patrick J. Dwyer, Isaac Flack, William J. Hill, James Horgan, Charles G. Knight, Samuel W. Kyle, Morgan Leane, Thomas J. McAllen, Samuel McCormac, Robert A. M. L. McCrea, Jerome B. Murphy, Joseph Nunan, Joseph A. O'Halloran, Maurice A. Power, William B. Purdon, Patrick Reid, Maria Rowan, Richard V. Slattery, B.A., Peter Walsh, Ernest J. Watson, and Jemina B. White.

THE Army Medical Service Advisory Board, the members of which are Sir C. B. Ball, M.D., Sir E. Cooper Perry, M.D., Sir Frederick Treves, Bart., K.C.V.O., F.R.C.S., and Dr. J. Galloway, has been appointed for a further period of three years.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES or LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**DR. HELFIELD.**—Your paper on Mediterranean Fever is unavoidably held over for want of space.

### THE BOSGIAN BOWL.

For salads *le d'avier cri* is flowers, something gay and pretty to adorn the bowl.—*The Lady.*

Fair to the sight that bowl may seem,  
Denked out with all the spoils of Flora,  
But what if its contents should seem  
With poppy blooms and mandragora?  
Talk spikes of foxglove charm the eye,  
But, though dished up *cum grano salis*,  
Few gourmets would consent to try  
A bowl of seasoned digitals;  
Or bear more love than even Shelly bore

T'ward hemlock, aconite, and hellebore!—*Truth.*

**EDINBURGH STUDENT.**—From inquiries made we understand there is not to be a new edition of the book at present, the authors considering it quite up-to-date.

**MR. WALTON CLARKE.**—It is a question outside the sphere of medical journalism, and we cannot undertake to reply.  
**DR. BOYD and DR. DUFF.**—See notice to Dr. Hefield.  
**MR. DAVID OWEN.**—Your communication came to hand as we were "at press," the subject will be dealt with in our next.

### IMPOSITIONS ON MEDICAL MEN.

This paragraph is written to prove that even a doctor will turn. A man called upon one not long ago to be examined. The doctor examined him and wrote out a prescription. When told what the fee was the patient asked to be allowed to owe the amount as he had been out of work for some weeks, and was short of funds. As he seemed a decent sort of fellow the doctor granted his request. The man profusely thanked him, and then asked what it would cost to have the prescription made up. On learning that five shillings would about cover it, he asked the doctor if he would supplement his kindness by lending him the money. That was just a little too much for the man of medicine. He seized the prescription from the patient's hand, and said, "This prescription, I'm afraid, my man, will not quite do in your case. I've been treating you for nerves."  
*Daily Chronicle.*

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 19th.

**ROYAL MICROSCOPICAL SOCIETY** (20 Hanover Square, W.).—8 p.m. Dr. D. H. Scott (President): Demonstration on the Reconstruction of a Fossil Plant.

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.). 4 p.m. Mr. C. Ryall: Clinique. (Surgical.) 5.15 p.m. Sir A. D. Fripp: Recent Variations in the Technique of Certain Common Operations.

THURSDAY, OCTOBER 20th.

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. P. Stewart: Facial Paralysis.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION and DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. J. E. Squire: The After-Effects of Pleurisy (Illustrated by cases). (Post-Graduate Course.)

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture: Mr. W. Edmunds: Diseases of the Prostate.

FRIDAY, OCTOBER 21st.

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Dr. H. Tilley: Clinique. (Throat.)

**SOCIETY FOR THE STUDY OF DISEASES IN CHILDREN** (11 Chandos Street, W.).—5.30 p.m. Cases will be shown by Dr. C. O. Hawthorne, Dr. B. Hutchinson, Mr. S. Stephenson, Dr. L. Guthrie, Mr. A. Edmunds, Dr. Cautley, Mr. G. Pernet, and others. Papers: Mr. A. C. Lucas: On an Ill-developed Upper Lateral Incisor Tooth as a Fore-runner of Harelip or Cleft Palate.—Dr. S. Gilford: On Two Cases of Congenital Diaphragmatic Hernia.

MONDAY, OCTOBER 24th.

**ODONTOLOGICAL SOCIETY OF GREAT BRITAIN** (20 Hanover Square, W.).—8 p.m. Mr. J. F. Colyer, L.R.C.P.Lond., M.B.C.S., L.D.S., Eng. "Some recent additions to the Museum of the Society." (Illustrated by Lanterna Slidea.)

TUESDAY, OCTOBER 25th.

**THERAPEUTICAL SOCIETY** (Apothecaries' Hall, E.C.).—4 p.m. Annual General Meeting. After which paper will be read by Dr. Harris: On some Therapeutical Applications of the Continuous Current.

## Vacancies.

**Horton Infirmary, Banbury.**—House Surgeon. Salary £200 per annum, with board and residence in the Infirmary. Applications to the Honorary Secretary, 21 Marlborough Road, Banbury.

**Darlington Hospital and Dispensary.**—House Surgeon. Salary £120 per annum, with board and lodging in the Institution. Applications to the Secretaries, 48 Stanhope Road, Darlington.

**Somerset and Bath Asylum, Cotford, Taunton.**—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications to the Medical Superintendent.

**Down District Lunatic Asylum.**—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, &c. Applications to the Resident Medical Superintendent.

**East London Hospital for Children and Dispensary for Women, Shadwell, E.**—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Applications to Thomas Hayes, Secretary.

**Devon County Asylum.**—Second Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent, the Asylum, Exminster.

**Wakefield West Riding Asylum.**—Assistant Medical Officer. Salary £140 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director at the Asylum.

**Bury Infirmary.**—Junior House Surgeon. Salary £200 per annum, with board, residence and attendance. Applications to the Hon. Secretary, Dispensary, Knowsley Street, Bury, Lancashire.

**The Municipal Corporation of Port Elizabeth.**—Medical Officer of Health. Salary £250 per annum. Applications to Davies and Soper, Agents of the Municipal Corporation of Port Elizabeth, 54 St. Mary-axe, London, E.C.

**Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.**—Senior House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to Robert J. Bland, Secretary.

## Appointments.

**BLACKFORD, JAMES VINCENT, M.D., B.S.Durh., L.R.C.P.Lond., M.R.C.S.,** Medical Superintendent at the City and County Asylum, Fishponds, Bristol.

**GUNN, ALBERT, A., M.B., Ch.B.Edin.,** Honorary Assistant Physician to the Blackburn and East Lancashire Infirmary.

**HEATCOTE, HENRY, CHARLES, M.B., B.Ch.Vict.,** Medical Officer for the Fawton St. Loe District by the Keynsham Board of Guardians.

**LEITCH, MORTON EDWARD, M.D. BRUX., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg.,** Medical Officer for the Lerryn District of the Liskeard (Cornwall) Board of Guardians.

**MARTIN, JOHN M. H., M.D.Vict., F.R.C.S.Eng., J.P.,** Honorary Consulting Surgeon to the Blackburn and East Lancashire Infirmary.

**MORGAN, THOMAS WHITWORTH SEWELL, M.B.C.S.Eng., L.S.A.,** Medical Officer for the Preston District by the Keynsham Board of Guardians.

**SAWYER, JAMES E. H., M.A., M.D. Oxon., M.R.C.P.Lond.,** Pathologist at the General Hospital, Birmingham.

**STEVENS, ROLAND A., L.R.C.P., M.R.C.S.Eng.,** Medical Superintendent at the London Open-air Sanatorium, Pinewood, Wokingham, Berks.

**WADMORE, J. CHRISTOPHER, L.R.C.P.Lond., M.B.C.S.Eng.,** Assistant Resident Medical Officer at the London Sanatorium, Pinewood, Wokingham, Berks.

## Births.

**ABRAM.**—On October 15th, at Reading, the wife of G. Stewart Abram, B.A., M.B., of a son.

**HARRIS.**—On October 16th, at 12 Buckingham Place, Brighton, the wife of Henry Arthur Clifton Harris, M.R.C.S., L.R.C.P., of a daughter.

## Marriages.

**ALINGTON—TOOTH.**—On October 15th, at St. Andrew's, Wells Street, Argentine Hugh Alington, Lieut. R.N., son of Admiral Alington of Swinhope, Lincolnshire, to Janet Marchant, daughter of Howard H. Tooth, M.D., C.M.G., of 34 Harley Street, London, W.

## Deaths.

**BRICKWELL.**—On October 16th, at Somerset, Huntingdonshire, Betsy, widow of the late Henry Brickwell, M.R.C.S., L.S.A., of Somersham.

**THORNTON.**—On October 16th, at 8, West Park Gardens, Kew, Jess Thornton, the widow of the late Philip Thornton, M.R.C.S.

## ROYAL CITY OF DUBLIN HOSPITAL.

A vacancy exists for the position of Gynecologist. Applications to be sent on or before 29th Inst., to the Hon. Sec., Medical Board, Mr. G. Jameson Johnston.

## Original Communications.

### THE LACK OF PRACTICAL METHODS IN MODERN SURGICAL EDUCATION. (a)

By EDMUND OWEN, F.R.C.S.,

Consulting Surgeon to St. Mary's Hospital, London.

FROM the intimate acquaintance which I have with William Hey, the illustrious founder of this Leeds General Infirmary, I feel convinced that if he could come back for a day or two and follow you about, he would say that the present system of medical education was unsatisfactory; and I feel equally sure that if he had been brought under this system, English surgery would have been robbed of one of its brightest luminaries.

Hey was enabled without any interference to devote the whole of his first winter to the practical study of anatomy. He seldom spent less than twelve hours a day at anatomy, which he considered as the foundation of surgical science. You would consider yourselves fortunate, I dare say, if you could manage to secure three hours on end in the dissecting-room—and even then you would probably be tempted to leave off in the middle of your interesting work in order to attend some demonstration, for you have been brought up in the belief that the knowledge of anatomy is best acquired by being *taught* it. This was not Hey's opinion. He was a practical anatomist at the beginning and always, and when he became a practical surgeon he still kept a close hold upon his anatomy. He was a most strenuous worker, and knew exactly how to set about his studies, and how to obtain the greatest advantage from them. "Being aware," says his friend, "of the disadvantage of engaging himself with a multiplicity of objects at the same period, it was his method to direct his *principal* attention to one subject at a time without, however, absolutely neglecting others when his leisure would permit." That is to say, when he was working at anatomy he might, if he could spare the time from it, attend a lecture upon some outside subject, but not otherwise.

Had he been living at the present time the Dean of his medical school would be told that he was not working at practical chemistry, or histology, or that he was not attending some course of lectures which absolutely failed to interest him, and from which he was unable to learn anything. If Hey had been a student at the present time he would have been strangled by the red tape with which he would find his course hampered.

#### FAILURE AT SURGICAL EXAMINATIONS.

A few months ago, the President of the Royal College of Surgeons, Mr. John Tweedy, called attention to the fact that students were not acquitting themselves as satisfactorily at their final examinations in surgery as was formerly the case; he regarded the matter as worthy of serious consideration, and he asked if any explanation of the fact were forthcoming, and if any-

thing could be done towards remedying it. In an attempt to answer this question, I would say, in the first place, that no equivalent has ever been devised for the old apprenticeship system, and, in consequence, every year the student's training is becoming less practical. We hoped that the "fifth year of study" was going to make good some of the deficiencies left in our scheme of education, but we have been grievously disappointed. I am not going to ask for a restoration of the apprenticeship system; to go back to it would be as undesirable as impossible; still the system was not without great merits, for it made a man quick, handy, and resourceful. It enabled him confidently to recognise and treat a fracture or dislocation, and to apply a splint and a bandage in a manner which would, I expect, put most of you to shame. The senior student of former days could bleed a man, and he could pass a catheter, and he might be trusted to do every operation in minor surgery long before he had begun to think of his final examination. But at the present day students are not *practical*. They fall lamentably short in their *clinical* work, up to which, I need hardly remind you, their entire educational course is supposed to lead. Their clinical knowledge is to be their chief future asset in their daily professional life, for the training of the medical student is not to make him a biologist, a chemist, or even an anatomist, but to teach him to recognise disease with precision, and to deal with it with satisfaction to the sick people under his care. I have no hesitation in affirming that, in these respects, the training of the medical student of to-day is not nearly as thorough and efficient as it was in the time of William Hey.

#### SURGICAL VENEERING.

The students of to-day are depending far too much upon "coaching." They seem to think that time spent in steady work at the bedside and with the patient might be more profitably employed in some special form of tuition. I regret to say that year by year they are coming less into personal contact with patients. They listen to demonstrations on cases; they discuss the problems of disease with their tutors, and they occasionally attend a clinical lecture, but actual work with the patients themselves is every year diminishing. The result is that they fail lamentably in the clinical part of their tests. They do not know how to set about investigating a case with a view to diagnosis. They do not understand, for instance, how to handle a case of hip-disease, and still less to estimate the amount of deformity at the joint. They do not know how to investigate a case of infantile paralysis, and many of them seem to have had no personal experience with the translucency test for hydrocele. All these methods of procedure are in daily use in the out-patient department and in the wards, where the senior students ought to be spending most of their time. But they are not there; they trust to acquiring a minimum clinical veneer at the "college-class." They tell me that they have not time for work in the wards!

In the course of a *visû voce* examination in surgery, with the object of making it a personal, living matter, and of getting a practical answer from the candidate, it was often my custom to introduce a subject thus:

(a) Abstract of an Address delivered to the students of the Leeds Medical School, October 15th, 1904.

"You have seen a case of so and so?" Then, on the candidate saying "Yes," I would ask him to describe the case and the treatment of it, just as if we were looking at it together in the hospital-ward. But of late I have had to give it up, because of the frequency with which the reply was that he had "never seen such a case." It is disheartening to an examiner to be told, for instance, that the candidate has never seen a case of infective osteo-myelitis. I can quite understand that a student has never seen a patient with erysipelas, or delirium tremens, for such cases are now promptly taken from a general ward and placed in beds which, are, unfortunately, far removed from the student's sphere of exercise. And I can realise the fact that he may never have seen a case of pyæmia, or of traumatic spreading gangrene, for the simple reason that surgical cleanliness has made such diseases—common enough in my student days—of comparative rarity. But the cases to which I refer are such as one constantly finds in a general surgical ward. "What! never seen a man with extravasation of urine?" "No." "What! never seen a case of renal calculus?" "No."

Ask any of your surgical friends who were students in the seventies and eighties if they found time for making a practical acquaintance with surgical cases, and you will probably be told that they spent a couple of hours in the wards in the morning with the house surgeon, and that they were there again, and in the operating theatre, for another two hours with the surgeon of the day, not only when they were dressers but subsequently, and that on many days they were hanging about the surgical department of the hospital until late in the evening. I have no doubt that many of you would adopt that plan if you were a little more masters of your time. But you reply that you have not time enough for all that you have to do.

#### THE "FIFTH YEAR."

"Not sufficient time?" says the student of former days. "Why, the General Medical Council have given you a *fifth* year of study; we had but *four* years!" Yes, this is true, but it has turned out a bitter disappointment. It has considerably increased the expense of medical education, but it has missed its mark entirely. It ought to have been made "the practical year," but the authorities have allowed it to be frittered away, and for all the practical, professional good that the medical student obtains from it, he might almost as well have spent it at school.

One of the chief reasons for students not having "sufficient time" for practical surgery is that many of them have been kept back by their chemical work. The examinations in chemistry for medical students suggest that the examiners think that chemistry is going to be the chief occupation of the individual when he is in practice. It is much the same with physics, and the sooner that its standing is placed at a common-sense level the better. The Medical Council have already accomplished so much in the cause of education that it is not improbable that they will ere long see fit to make some change in the direction of greater freedom, and one which will help towards securing for the student an increasing store of *practical* knowledge.

On all sides I hear complaints of this want of practical knowledge on the part of those who have recently obtained their qualification. Thus, a general practitioner finds himself in need of an assistant, and he applies to some friend upon the staff of his old hospital to send him a likely man. In answer to his application one of the most promising students is sent, one, may be, who took the prizes in biology and chemistry. But in a little while the practitioner writes to say that the so-called "assistant" is no help whatever; that though he is an adept in the art of prescribing drugs of doubtful value but of undoubted expense, he knows, *practically*, nothing of his profession; that he cannot be trusted in anything; that all his work must be closely supervised; that his diagnoses are as extra-

vagant as they are improbable; and that though he can talk eloquently about Bassini's operation he cannot diagnose a simple hydrocele; that he mistakes scarlet fever for measles, and swollen cervical glands for mumps; that he treats the diarrhoea of intestinal cancer with chalk and opium (without ever thinking of making a digital examination of the rectum); and that he applies a fomentation to the painful knee of a boy with early hip-disease.

Let me urge upon you to get through your preliminary science examinations as quickly as possible, so that you may the longer occupy yourselves in clinical work. Do your best to attend regularly in the out-patient department, and never for one moment fancy that you are wasting time because so few of those applying for relief are the subjects of diseases of an unusual type. When you get into actual practice the experience thus acquired will prove far more serviceable to you than that which has been obtained in listening to clinical lectures upon certain rare cases, or, may I say it, than the instruction which you obtained in "special classes"!

As things are, the dreaded examination becomes due before the candidate is ready to meet it. He feels that he does not know his work, but he is under the impression that the most likely way of leading his examiners to think that he does is by obtaining a surgical polish at the hands of an experienced "coach." This gentleman is probably an able and energetic young surgeon, who has already acquired considerable reputation both as a student and a teacher, in addition to which he is possibly regarded as an astrologer of some merit. That is to say, by making a prolonged and careful study of the past examinations, he has acquired the art of guessing what questions are going to be set at the forthcoming one. He has, in other words, elaborated a "system," which sometimes works out with extraordinarily good results. But the literary style imparted by some of these coaches—if I see it correctly reflected in the paper-work of their pupils—is not a high one. For a very favourite method of writing an answer to a question consists in drawing one or two straight lines vertically down the folio, and inserting in the respective columns the symptoms of one disease as compared with those of another, or the headings of the schemes of treatment appropriate for them. This method is constantly recurring in answer to questions involving differential diagnosis, the columns being as destitute of verbs as are the pages of an auctioneer's catalogue. I do not know how this method originated, but I rather think that certain coaches, in the endeavour to impart knowledge, tabulated, exact and concentrated, plan out their teaching in this manner upon a blackboard in front of the class. It is science in the tabloid form. Some of the papers written by senior students would, so far as literary merit is concerned, scarcely reflect credit upon a pupil from a Board School, and if I might presume to address a few words to "coaches," I would say that unless they themselves write decent English they cannot impart the art to their students. And if they deign to inquire to what source I would refer them for style, I would say, the Gospels, the "Pilgrim's Progress," and the "Sentimental Journey."

The current style of English medical literature is, for the most part, tedious to the last degree, and now that dear old Mitchell Banks' pen is for ever dry, there are few to brighten the pages of our journals and to charm the reader.

You should make an attempt at style even in your ward-notes; and so, later on, when you are preparing a full account of your own extraordinary success in the treatment of a series of medical cases with some new and fashionable drug (and you must be quick, for new and fashionable drugs are soon found to have lost their efficacy), or some wonderful results obtained in operative surgery, take pains with the preparation of your paper, and if you cannot make it attractive, at least make it readable—and not too long.

By the present scheme of education far too much

*teaching* enters into the daily life of the medical student. He is lectured to, catechised, and crammed until a sort of intellectual dyspepsia is induced in him, and he is unable to *learn*. Moreover, from want of proper mental exercise, he has almost lost the desire to learn. All his intellectual food is served to him hot, finely divided, and peptonised. His wisdom-teeth are of no further use. He goes up for his practical examinations at regular intervals, and he comes back rejected. "Poor fellow," say his friends, "how unlucky he is! He certainly deserves to pass, for he is such a steady worker."

I was once asking a candidate to describe the operation of herniotomy, and his description ran thus:—"Then you enlarge your wound and expose your sac"; and, later, "Then you separate your omentum from the wall of your sac." I maintain that when a candidate is asked to describe his method of treatment he has no right to use this second personal pronoun. When I have put my question I want the answer to suggest, as it were, the candidate performing the very operation step by step. Again, I was asking a candidate to describe the early stages of a certain disease, and he said, "And then your inguinal glands become enlarged, and you break out in secondaries"! When I asked him to be somewhat more impersonal in his reply, it did not seem to dawn on him that he had been thoughtless, for he quickly went back to the use of the second personal pronoun, and did not leave me until I was a hopeless physical wreck!

"Oh," says the candidate, in answer to the question as to what treatment he would advise in a case of diphtheritic disease of the knee-joint, "you might try"—notice the pronoun and the auxiliary verb—"Scott's dressing." When asked what Scott's dressing is, he has not the least idea. Asked how he would treat a case of mammary carcinoma with wide-spread implication of the cervical glands, he replies, "'You' might remove the breast"!

Ought a man who talks like this to be trusted in actual practice?

I do not condemn altogether the so-called college-classes and the special instruction classes. Possibly the system of education and the exigencies of examinations have rendered them almost a necessity; and it may be that, to a limited extent, they perform a useful function in our schools. But what I must insist on is that students ought not to be encouraged to place as much reliance on them as they do at present. For though they may help a man to scrape through an examination, they ought not for a moment to be regarded as the chief means of obtaining the minimum amount of a working knowledge of surgery likely to satisfy official tests, and still less of equipping him for actual practice. But I regret to say that of late years it has become the custom for the hard-pressed student to desert orthodox clinical methods, and to consider as their equivalent, if not their superior, the cram-classes of the surgical coach.

## ON THE TREATMENT OF INTRACTABLE PROLAPSE BY EXTIRPATION

### OF THE UTERUS AND VAGINA. (a)

By CHRISTOPHER MARTIN, M.B., F.R.C.S.

EVERY gynaecologist who has much hospital experience must have had cases of severe total prolapse of the uterus and vagina, which are intractable to ordinary measures, cases in which no pessary can be retained, and in which the ordinary plastic and suspensory operations fail to give more than temporary relief. It was such a case that

led me in 1899 to devise and perform the operation of extirpation, not only of the uterus but also of the whole of the vaginal canal, as a radical cure. I have now carried out this proceeding in four cases. The final after result has been excellent, and the cure of the prolapse complete. It is, however, a very severe remedy. The operation is a long, tedious and bloody one, and attended with a good deal of shock. There is a considerable danger of wounding the bladder, the ureters and the rectum. Convalescence, in all my cases, was slow and complicated with suppuration in the depth of the pelvis. I should only, therefore, feel justified in recommending this operation in cases where other and milder measures have been tried and have failed, and where the patient's discomfort is very great. It is to be kept in reserve as a *dernier ressort* and not performed as a routine line of treatment. For obvious reasons it should not be performed in married or marriageable women.

I do not propose to discuss at length the treatment of ordinary prolapse. In a great majority of cases all that is required is a well-fitting pessary, and for marked procidentia I know of no instrument so satisfactory as Simpson's shelf pessary. When no pessary can be retained, or where the patient objects to its use, a plastic operation should be performed to support the uterus. In such cases I am in the habit of doing ventro-fixation of the uterus combined with an extensive colpoperineorrhaphy. The results, as a rule, are very satisfactory. Occasionally, however, it will be found that the uterus breaks away from the abdominal wall, or remains attached to it merely by a long thin band of adhesions, or becomes elongated and stretched, so that whilst the fundus is still adherent to the anterior abdominal wall, the cervix is outside the vulva. At the same time the vagina gradually dilates, the perineal scar stretches, and slowly the condition of total prolapse becomes re-established. In such cases vaginal hysterectomy may be performed. But whilst it is obvious that if the uterus be removed it can no longer be prolapsed, the operation does not cure the rectocele and cystocele. In one case in which I performed vaginal hysterectomy for prolapse, the vagina afterwards protruded as a large, polony-like swelling and turned completely inside out.

We may now pass on to a brief description of the object and the steps of the operation of extirpation of the uterus and vagina. The main aim of the operation is, after removal of the uterus and vagina, to bring together the fascia of the pelvis in such a way as to make a firm fibrous diaphragm extending from one side of the pelvis to the other, and having adherent to it the bladder in front and the rectum behind. In this way a firm, solid, pelvic floor is built up, measuring in depth from peritoneum to perinæum some three or four inches. We produce, in fact, a pelvic floor closely resembling that which obtains in the male pelvis.

In its broad outlines the operation closely resembles that of the radical cure of hernia. Thus the contents of the hernia are removed, the peritoneum is closed, the fascia is brought together with buried sutures, and finally the cutaneous wound is closed.

The patient should be kept in bed for several days before the operation, the functions of the stomach and the bowels regulated, and her general health

(a) Read at a meeting of the British Gynaecological Society, and specimen shown, October 18th, 1904.

improved as much as possible. The vagina should be rendered as aseptic as possible by frequent antiseptic douches. Should the prolapse be irreducible, the parts should be well washed with soap and water and lysol, swabbed with methylated spirit and then wrapped in gauze or lint soaked in a solution of biniodide of mercury. If, as is often the case, the cervix or vagina be ulcerated from friction against the patient's clothes, an attempt should be made before the operation to get the ulcers healed by keeping the patient in bed and applying antiseptic dressings. If any ulcers remain they should be swabbed with pure carbolic acid at the commencement of the operation.

The patient having been anæsthetised and placed in the lithotomy position, the vulva, the vagina and cervix are again thoroughly cleansed with lysol, followed by spirit and biniodide of mercury.

The cervix is seized with vulsella and drawn forwards. An incision is made in the mesial line through the vaginal mucous membrane from the posterior lip of the cervix to the edge of the perinæum. From the latter point two curved incisions are carried forward, one on either side at the junction of the vaginal mucous membrane and the skin of the labium, meeting in front about half an inch behind the meatus urinarius, that is, near the posterior edge of the vestibule. It will be seen that these incisions completely encircle the ostium vaginæ, and roughly correspond to the line of attachment of the hymen.

The mucous membrane of the posterior and lateral vaginal walls is now dissected off with scissors and turned forwards, but at this stage the mucous membrane of the anterior vaginal wall is not interfered with. The peritoneum of the pouch of Douglas is next opened by a transverse incision, and the fundus of the uterus exposed and drawn downwards. The broad ligaments are ligatured and divided from above downwards, either internal to or external to the ovaries and tubes. Should a ventro-fixation have previously been performed, the attachment of the fundus to the abdominal wall must be severed with scissors.

The fundus having been seized with forceps is drawn downwards, acutely retroflexing the uterus, and exposing the bottom of the utero-vesical pouch. The peritoneum at the bottom of this pouch is divided transversely and the bladder stripped off the cervix with the finger. The mucous membrane of the anterior vaginal wall is next dissected off the bladder and urethra with scissors and removed, together with the uterus, in one piece. This separation of the anterior vaginal wall is the most difficult and tedious part of the operation, and unless great care is exercised the bladder or ureters may be wounded. It usually causes free hæmorrhage from the veins of the vaginal plexus.

Each bleeding point must be seized and ligatured with fine silk or catgut. It is very important to control all hæmorrhage completely before proceeding with the next step of the operation. In every one of my cases there has been a collection of grumous pus, due, I think, to the breaking down of blood effused from these numerous small veins. All bleeding having been controlled, the abdominal cavity is closed by a purse-string suture of fine silk passed through the peritoneum of the pouch of Douglas, the back of the bladder, and the top of the broad ligaments.

Below this purse-string suture the broad ligament

of one side is sutured to that of the other with fine chromicised catgut. Below this the pelvic fascia of one side of the pelvis is sutured to that of the other side of the pelvis with fine interrupted chromicised catgut, beginning above at the base of the broad ligaments and working gradually down to just above the vulva. In this way a firm diaphragm, stretching from one side of the pelvis to the other and supporting the bladder in front and the rectum behind, is built up of connective tissue derived from the pelvic fascia. This is really the most important part of the operation. I do not attempt to suture the bladder or the rectum to this fascia. They afterwards become firmly attached to it.

The vulva and wound are then closed with fine silkworm-gut sutures which approximate the posterior halves of the labia.

If the hæmorrhage from the deeper part of the wound has not been completely arrested, I should recommend the insertion of two small rubber drainage-tubes, one in front of the fascial column and one behind it. These should be removed at the end of twenty-four hours.

The vulva is dusted with iodoform and a pad of iodoform gauze is applied. The patient's urine should be drawn off with a catheter for about a week, and she should be kept in bed for about three weeks.

As I have already said, it is a long and difficult operation and is attended with a good deal of risk to the patients, who are, as a rule, elderly women and often in feeble health. The prolapsed cervix and vagina are apt to be ulcerated from friction against the patient's clothes, and the discharge from these ulcers may lead to infection of the wound and suppuration. There is free hæmorrhage during the course of the operation, not so much from a few arterial trunks but from the numerous veins of the vaginal plexus. There is considerable risk of wounding the bladder, the ureters and the rectum. After the operation there is a good deal of shock, and shock in old, feeble women is a serious matter. The convalescence is apt to be a tedious one, and in all my cases was complicated with deep-seated suppuration in the wound. The after results, however, are excellent, and to my mind justify me in recommending this operation in suitable cases. Let me now very briefly refer to the four cases in which I have performed the operation.

CASE I.—Mrs. K., a widow, æt. 53, was sent to me by Dr. Leech, of Birmingham, suffering from stone in the bladder and complete prolapse of the uterus. She had evidently had the stone for a long time, and the straining which it gave rise to no doubt aggravated the prolapse. I took her into the Women's Hospital at Birmingham, and on July 22nd, 1895, removed a large calculus by the operation of vaginal cystotomy. The incision healed by the first intention. On August 16th in the same year, I performed the operation of ventro-fixation, together with perineorrhaphy. The wounds healed well, and the result was satisfactory for about two months. In November, 1895, she began again to have some cystocele, and I inserted a small pessary. Gradually the prolapse of the anterior and posterior vaginal walls recurred, and in spite of pessaries of all shapes and sizes became total. In October, 1896, the vaginal prolapse was so marked that I again took her into the hospital and performed extensive anterior and

posterior colporrhaphy together with perineorrhaphy. As before, the immediate result was satisfactory, but it was only for a time. In January, 1897, the cystocele recurred, and I had again to resort to pessaries. From this time onwards, she attended as an out-patient with steadily increasing prolapse until, in 1899, the uterus was once more quite outside the vulva, the vagina turned completely inside out and ulcerated from friction against the clothes. I then decided to perform total extirpation not only of the uterus, but of the whole vagina. I explained to the patient exactly what I proposed to do and she readily consented to have anything done that would afford her relief and enable her to carry on her work, that of a charwoman. The operation was performed on May 11th, 1899. The patient was put back to bed in a state of collapse, but rallied after free stimulation with ether, brandy, and strychnine. After this she continued to progress satisfactorily until about the tenth day, when her temperature began to show a marked evening rise and morning fall. This continued until the fourteenth day, when it reached 103° F. A pair of sinus forceps were then thrust into the depth of the vaginal wound, and a large collection of grumous pus (evidently broken down blood) evacuated. After this, she made a straightforward recovery, and left the hospital on the twenty-fourth day. After leaving the hospital she continued to improve, and when I saw her again, on June 30th, she was quite well. I examined her in the early part of July, 1901, and found her condition most satisfactory. She was perfectly comfortable, and had complete control of the bladder and rectum. The vulvar scar was firm and quite painless, and in her own words, "Life was now a pleasure instead of a continual misery." Since then I have seen her from time to time (the last occasion being October 10th, 1904). She has remained perfectly well and is very comfortable.

CASE II.—Mrs. J. L., æt. 56, was sent to me by Dr. Simpson, of Rugby, suffering from extreme prolapse. She was a widow and earned her living as a cook. She had had one child over thirty years ago. There was a history of gradually increasing prolapse for over twenty years. She had worn in turn instruments of various kinds (Hodge, ring, cup and stem, shelf, and Gariel's ball pessary). Finally, nothing would stay in, and she had to support the totally prolapsed uterus with a diaper. In June, 1901, she underwent a plastic operation on the perinæum at one of the London hospitals; but this gave only a very temporary benefit. On October 17th, 1901, I performed total extirpation of the uterus and vagina. For the first ten days the patient made a good recovery. Then her temperature began to go up at night to 101° or 102°, with morning remissions. Her pulse was never over ninety-five. I evacuated some pus with the sinus forceps on the fifteenth day. After this she did well and went home on November 19th, four and a half weeks after the operation.

I saw the patient on December 17th, and again in February, 1902. She could walk well, and go up and down stairs without any discomfort. There was no feeling of bearing down. She had no discharge and the bowels and the bladder acted normally. The vulvar wound was strong and firm, and showed no signs of bulging when she strained. She returned to her work as a cook and I hear has since remained well.

CASE III.—(Specimen).—Mrs. E. M., a widow, æt. 45, was sent to me by Dr. Baldwin, of Birmingham. The uterus was totally prolapsed and the cervix ulcerated. There was a constant discharge of blood and of muco-pus. Thirteen years before she had been operated on by another Birmingham surgeon, who repaired her perinæum. I found it impossible to insert any pessary, and the condition was so bad that I decided to extirpate her uterus and vagina. The operation was performed on November 22nd, 1902, when I removed her uterus, ovaries and tubes, and the whole of the vagina. The operation was performed in the method already described. The broad ligaments were ligatured with silk, the pelvic fascia sewn with chromicised catgut and the vulvar wound with silk-worm-gut. The patient did not make a good recovery. Her temperature went up the second day and fluctuated for some days between 99° and 102°. The deeper part of the wound became infected. Finally, a pair of sinus forceps were thrust in and a deep collection of pus evacuated. After this, she progressed quite satisfactorily, and left the hospital on December 28th, five weeks after the operation. The wound had then healed and all discharge had ceased. I saw nothing of her until April, 1903, when she came to the hospital complaining of discharge from the vulva. On examining her I found a deep sinus in the perinæum. I took her into hospital again and explored this sinus under chloroform, and was able to fish out some buried chromicised catgut sutures, which had become infected and had not been absorbed. After this, the sinus healed up and the patient's condition improved.

I last saw her about a week ago, and then found she had still a little discharge and that the vulvar cicatrix was red and irritable. Although she was infinitely better than she was before the operation, I suspect there is still a buried suture in the septum between the rectum and the bladder causing irritation. This case was the least satisfactory of the series.

CASE IV.—Mrs. J. L., a widow, æt. 63, was sent to me by Dr. Cowen, of Malvern. She had had prolapse for over twenty years. Many years ago Mr. Lawson Tait repaired her perinæum, but in about a couple of months the cicatrix stretched, and she was soon as bad as ever. She wore numerous instruments (such as rings, balls, cup and stem, and shelf pessaries), but nothing would keep in. During the last few months the parts have been badly ulcerated from friction. When I examined her I found the uterus totally prolapsed, and the vagina turned inside out and ulcerated. On February 29th, 1904, I performed total extirpation of the uterus and vagina, but did not remove the ovaries or tubes. The peritoneum and broad ligaments were sutured with fine silk, the pelvic fascia with gossamer-gut, and the vulva with silk-worm-gut. A small rubber drainage-tube was inserted into the posterior angle of the wound. It was a tedious and bloody operation and the patient was put back to bed rather collapsed, but rallied on free stimulation. Her temperature remained normal for the first fortnight. On the fifteenth day it rose to 100·6°, and two days later a free discharge of blood and pus took place from the wound. After this, she made a straightforward recovery; she got up on the twenty-third, and left the hospital on the twenty-sixth day after the operation.

I last saw her on April 25th, about two months after the operation. The wound was completely healed, she had no discharge, and no pain nor discomfort of any kind.

In relating the cases I have not attempted to minimise the dangers and drawbacks of the operation, and shall be glad of any suggestions or criticism from members of the Society which would improve the *technique*. In particular I shall welcome any suggestions which will help me to prevent the occurrence of the troublesome suppuration which complicated the convalescence of all my cases, and which, to my mind, is the chief disadvantage of the proceeding. I hope, however, in any future case to avoid this suppuration by more careful disinfection of the field of operation, by more careful arrest of hæmorrhage, by the use of drainage-tubes to prevent discharges collecting, and by the employment of perfectly sterile absorbable suture material.

Curiously enough, Dr. Edebohls, of New York, devised and performed an almost precisely similar operation in April, 1900, nearly twelve months after my first case. His description of the operation appeared in the *New York Medical Record*, on October 12th, 1901; while I published an account of my first operation in the *British Medical Journal* on October 5th, 1901, just one week before Dr. Edebohls. So that I feel that whatever merit there may be in the operation must be shared by Dr. Edebohls, who quite independently planned and carried out the same surgical operation.

### THE TREATMENT AND CLASSIFICATION OF PAUPER CONSUMPTIVES IN IRISH WORKHOUSES. (a)

By ALFRED E. BOYD, M.B., D.P.H.,  
Hon. Sec. of the National Association for the Prevention of Tuberculosis, Dublin Branch.

TUBERCULOSIS, a disease which is now known to be preventable, is still in Ireland the most common cause of death.

During 1902, the last year for which corrected figures are available, 11,837 persons died of this disease in Ireland as compared with 12,335 in 1901, and an average of 12,716 annually in the ten years 1891-1900. The death-rate for 1902 was 2.7 per 1,000 of the population as against 2.8 for 1901, and an annual average of 2.8 for the ten years 1891-1900. The highest county rates were—Dublin county borough, 4.7 per 1,000; Belfast county borough, 4.0; Dublin county, 3.5; Cork county and county borough, 3.0. The lowest were Cavan, 1.5; Roscommon, 1.6; Mayo, Fermanagh, Longford, and Donegal, each 1.7. The rate for all forms of tuberculous disease in the urban districts having a population of 10,000 and upwards was 4.1 per 1,000, while in the rural districts it was 2.1 per 1,000.

Speaking generally then, tuberculosis is a disease affecting urban rather than rural districts, and the eastern rather than the western counties of Ireland. Of the 11,837 deaths from tuberculosis registered in 1902, consumption, its commonest manifestation, caused 9,400 and of these 1,303 died in our workhouses. Half the total number of deaths in

all Ireland of those between 15 and 35 years of age are caused by consumption; the death-rate, therefore, is but a poor indication of the misery arising from this dread disease. In the words of Mr. Culverwell, Fellow of Trinity College, Dublin, "it is the adult, the wage earner, the man who has incurred the responsibilities of life, the man to whom a family looks for support, or the mother on whose care the welfare of young children depends, who are its most frequent victims." These are taken, often after a prolonged struggle, and those dependent on the victims are too often left without the means of support and become a burden to the rates. Again to quote Mr. Culverwell—"Assuming that on an average each of the 12,000 people who die annually in our country of tuberculosis is worth only 5s. a week to the community, and that he would live for ten years longer if there were no tuberculous germ in Ireland, then each death is a loss of over £130, and the total loss is 12,000 times this or £1,560,000 a year." (a)

Apart from all considerations of humanity and Christian charity, it is in the interest of everyone to do what in him lies to check this appalling wastage of national capital and to preserve to our country the flower of Irish manhood.

Patients suffering from this disease are now denied—and rightly so—admission to our general hospitals, because it is recognised that consumption is an infectious disease, a slow fever, conveyed from man to man, most usually by the inhalation of the dried expectoration of consumptives in the form of germ-infected dust, or of the spray scattered by consumptives in the act of coughing.

There are no sanatoriums in the country available for the very poor, although we hope soon to see at least two at work, in Cork and Belfast respectively, and were there such they would still leave the advanced cases, those, in fact, who are most dangerous to the community, unprovided for. The Homes for the Dying and Incurable can only accommodate a small proportion of such cases, the great majority must therefore perforce seek relief in the workhouse infirmaries or remain at home, usually sleeping in the same room, too often in the same bed, with their relatives, to whom their presence is a constant source of danger. No wonder, then, that consumption "runs in families" as the result of this constant exposure to the risks of infection in the home, and that the disease was deemed to be hereditary until its true nature was revealed by modern science.

In what direction, then, is reform needed in order that the Irish Poor-law system may deal adequately with its responsibilities in regard to this problem of the housing and classification of the consumptive poor? The first essential is that provision should be made in all workhouses for the complete isolation of consumptives from other patients, and for their classification—those in whose case there is prospect of amelioration or cure being separated from those in whom the disease is advanced and whose case is hopeless. In over one half of the unions in this country separate accommodation is now provided, and in this respect greater success seems to have been achieved by the Irish Local Government Board than by the kindred body in England, where the proportion of Boards doing anything in this matter

(a) Paper read at the Conference of the Irish Workhouse Association, held at Limerick, October 5th, 1904.

(a) "Consumption: its History and How to Prevent its Spread." E. P. Culverwell, F.T.C.D.

is said to be under 18 per cent. There still remains, however, the grave objection felt by so many of the respectable poor to availing themselves of treatment in workhouse infirmaries unless driven thither by dire poverty, and the consequent numbers of sufferers remaining in their homes and proving sources of infection to others.

In any scheme for the amalgamation of Poor-law unions, provision could surely be made for the setting apart of existing buildings, where such are suitable for the reception of consumptive patients, and for the remodelling of at least a portion of each building so set aside, so that it might be suited to the carrying out of open-air treatment in such cases as are likely to derive benefit from the method. The degrading associations of pauperism being removed, many who now regard the workhouse infirmary with abhorrence would gladly avail themselves of treatment under circumstances far more hygienic than they can command at home, while many of those who are beyond hope of cure would willingly submit to segregation for the sake of those dear to them, when the risks of their staying at home are made clear to them.

In many instances, however, existing buildings could not be satisfactorily adapted to suit modern open-air methods without considerable expenditure of money. In such circumstances I would venture to suggest that the method now being tried at the great Poor-law infirmary at Stobhill, Glasgow, might be followed. Advanced cases there are kept in isolated blocks, while suitable cases in the early stages of the disease, where the prospect of improvement is good, are treated in tents on the lawn of the infirmary. Each tent holds six beds and the patients pass all their time practically in the open air. The capital expenditure involved as regards these patients is trivial, and their cost to the ratepayers is merely that of maintenance. A similar method has been followed during the past few months at the Royal National Hospital for Consumption at Newcastle, co. Wicklow, as well as elsewhere. The results obtained have been hopeful and the patients soon get used to their outdoor life. This method seems to me to offer more prospect of efficiently treating great numbers of consumptive poor than can be achieved by any building scheme involving large capital outlay, while the delay which the erection of buildings entails is entirely obviated.

If, however, existing buildings are capable of being remodelled, and if the conditions as regards surroundings, subsoil, protection from prevailing winds and sufficiency of sunshine are favourable, French windows might be substituted for those at present in use, and these should be made to open on to light iron-work verandahs, or galleries on to which the patient's bed may be wheeled on suitable days at the discretion of the nurse in charge, acting on the instructions of the medical officer.

As an example of the cost of such alterations it may be mentioned that the Bath Board of Guardians have allocated two wards—for males and females—for the accommodation of twenty consumptives. These wards have been altered and made suitable for carrying out open-air treatment. They have separate airing courts in which are placed shelters and dining-rooms, so that those who can leave their beds may remain out in these courts practically all day. All this has been done for an initial expenditure of £1,900, which has been borrowed with the sanction of the Local Govern-

ment Board, repayment being spread over a period of ten years. (a)

Where no suitable buildings are available for treating cases with a view to cure, and if the idea of keeping patients in canvas tents is scouted as impracticable, resort must be had to building. All such schemes are costly; thus the Eastby Sanatorium of the Bradford Board of Guardians, which is built on the pavilion system, and which when finished is to accommodate 42 patients, will cost, it is estimated, £221 per bed.

The West Derby, Liverpool, and Toxteth Park Joint Poor-law Hospital for Consumption provides accommodation for 24 patients, the average cost per bed, exclusive of land, being £338. If, however, the number of beds is increased, the average cost of each will be materially reduced, as the administrative block has been included in the buildings already erected. (b)

Dr. Reinhardt estimates that a sanatorium built on the chalet principle to accommodate 100 patients can be erected at an average cost of £100 per bed. (c) Speaking generally, the most feasible scheme seems to be the amalgamation of Unions, the setting free of one set of buildings for the use of consumptives of the joined area, the separation of the incurable from those in the early stages of the disease, and the treatment of the latter in wards adapted to open-air requirements, in tents or in open-air revolving shelters as each individual case may seem most suited to. The initial cost of such a scheme need not necessarily be great, while in the long run its provision would be true economy in preserving life among those already consumptive and in preventing the spread of the disease among the community. Without some such scheme how can the poor be treated with any reasonable hope of arresting the disease? And how can they be kept from being factors in the spread of infection?

The isolation of consumptives and their treatment under special conditions removes from the community the chief source of the spread of the disease, while the educational effect on the public of the means taken in well-managed institutions to prevent infection must have a wide-spread influence in checking its development.

In conclusion, let me remind you that this disease is one of the two great causes of the decrease of the population of our country.

We lose 40,000 each year by emigration, and 12,000 from tuberculosis. Those who are lost to the country from both causes belong to the same class—they are those in early adult life. There are factors at work in the industrial life of our country, which we all hope will have an influence in checking the national loss arising from emigration.

May I express the hope that the other great source of the decrease, the prevalence of tuberculosis, arising as it does in great measure from neglect and ignorance in bygone years, may receive that attention from our public bodies which it deserves and that the means by which its prevalence is being decreased in other lands may soon be adopted throughout our country? If our boards of guardians and sanitary authorities work hand in hand, if they act promptly and energetically, the death-rate from this cause can be materially

(c) "The Health Resort," October, 1903.

reduced, and a corresponding decrease in misery and pauperism will ensue.

### Clinical Records.

#### CANCEROUS UTERUS REMOVED BY COMBINED VAGINAL AND ABDOMINAL HYSTERECTOMY. (a)

By WILLIAM DUNCAN, M.D., F.R.C.S.

THE uterus shown was removed from an exceedingly stout nulliparous lady, *æt.* 42, who consulted Dr. Duncan in July last for menorrhagia, which had lasted four months. She had been twice married; fifteen years ago she consulted Dr. Duncan for the same condition, when the uterus was dilated and curetted. A mucous polypus was removed and a complete cure resulted. On examination *per vaginam*, the vagina was very small; cervix uteri healthy; sound passed 3½ inches, and caused bleeding (the patient was so stout that a bimanual examination was not possible). She looked healthy and well, and suffered no pain or offensive discharge. On dilatation of the uterus under anaesthesia, the curette brought away a lot of cheesy material; this was examined by Mr. Targett, who reported: "These curettings from the interior of the uterus are thickly infiltrated with a soft columnar-celled carcinoma of the villous type." A week later Dr. Duncan removed the uterus by hysterectomy, and as the vagina was so very small and the patient so stout, he adopted the combined method. When anaesthetised the patient was placed in the lithotomy position and an incision made all round the cervix; the bladder was separated up, and Douglas's pouch opened. Next the abdomen was opened, and the uterus removed in the usual way, but with the greatest difficulty owing to the excessive thickness of the abdominal walls and also to the fact that the broad ligaments were very short and did not allow the uterus to be pulled up much. The patient had a normal temperature on the eighth day. Dr. Duncan thought that perhaps it would have been easier to have cut through the perinæum to the anus and then have performed vaginal hysterectomy (as he has done on other occasions) rather than to have adopted the combined method.

#### CYST OF THE RIGHT FALLOPIAN TUBE (? ECTOPIC GESTATION). — DOUBLE TWIST IN THE PEDICLE AND COMMENCING NECROSIS OF CYST WALL. (a)

By BEDFORD FENWICK, M.D.,  
Physician to the Hospital for Women, Soho Square.

THE patient was *æt.* 46, unmarried. Menstruation commenced at 14, and has been perfectly regular every twenty-four days, lasting three days, and otherwise quite normal. She came to the Out-Patient Department of the Hospital for Women, Soho Square, on October 6th, stating that in August last the period was fifteen days late, lasted four days, and was very scanty, ceasing on September 5th, since which time she had seen nothing. On September 30th, she had a sudden, severe pain in the lower part of the abdomen, lasting three or four hours, and gradually passing off. On the morning of October 6th, the same pain suddenly returned and became very severe. On examination, the vagina was found to be large and

(a) Read at a meeting of the British Gynaecological Society, and specimen shown, October 18th, 1904.

lax, a tense swelling was felt in front of the uterus, fixed and extremely tender. Her temperature was 103° F., pulse, 110. She seemed very ill, and was at once sent into the wards, and I performed abdominal section the next day. The uterus was pushed down into the pelvis by a cystic swelling, thick-walled and perfectly black in colour; it was attached by soft recent adhesions to the bladder in front and the uterus behind. A pint of black blood was drawn off from it, and the cyst lifted out of the abdomen, and it was then found to have a long pedicle, twice twisted. On removal, a small, black ovary was found adherent to the outer edge of the cyst wall, and the cyst itself was found to be a dilatation of the outer third of the right Fallopian tube. There was no rupture, but there was commencing peritonitis. The left tube and ovary were perfectly normal. The sac seems lined with membrane, and contains apparently some firm, organised clots; but as it may be the wish of the Society to refer the specimens to a pathological committee, I have not disturbed these in any way. It will be observed that the tube is extremely constricted about one inch from the cornu of the uterus, where the double twist was found, and the surface of the cyst is perfectly black, and shows signs of commencing sloughing of its wall.

The important question arises as to whether this is a simple hæmato-salpinx or an ectopic gestation. In favour of the latter, is the dilated condition of the vagina, the definite and large dilatation of the outer third only of the tube, not of its whole length, and the considerable quantity—at least one pint—of blood which it contained. Presuming that further investigation proves this supposition to be correct, I need scarcely point out the rarity of the case. I can only remember having seen one similar example, and it must, therefore, be most unusual. It is further interesting to observe the rapidity with which necrosis and peritonitis were being induced, and the extreme danger which the patient would have suffered if she had not been immediately operated upon. She made an uneventful recovery.

### Transactions of Societies.

#### BRITISH GYNECOLOGICAL SOCIETY.

MEETING HELD OCTOBER 13TH, 1904.

Professor JOHN W. TAYLOR, F.R.C.S., in the Chair.

#### SPECIMENS.

DR. BEDFORD FENWICK showed as a strangulated ectopic gestation a necrotic sac removed from a single woman, *æt.* 46. The operation had been performed under the diagnosis of ovarian cyst, though certain points in the history pointed to extra-uterine gestation. He had met with one very similar case, and as he thought the Society might wish to refer the specimen for an independent pathological report, he had not himself made any section of the sac. Notes of the case will be found on this page ("Clinical Records").

After some remarks from Dr. DAUBER and the PRESIDENT, it was agreed that the specimen should be referred to a pathological committee.

Dr. FREDERICK EDGE showed the following specimens:—(1) Microscopical section from a case of glandular carcinoma of both ovaries removed with perfect immediate result, but with fatal recurrence within four months. The patient was *æt.* 48, and, apart from the tumours, was in good health and condition. The operation was performed at the Women's Hospital, Birmingham, on May 26th, 1904. The tumour on the

right side extended to the liver, and was of peculiar shape, resembling a vegetable marrow with one side pushed into concavity; the pedicle on this side was broad and fleshy, no doubt owing to increase in the muscular tissue of the broad ligament, and he therefore divided it and secured the vessels separately. The other tumour was much smaller and was tied straight off. Any adhesions were omental and all bleeding points were secured; no drainage was used, and the patient made an easy and uninterrupted recovery. On August 17th, in Dr. Edge's absence, the woman was readmitted into the hospital by his colleague, Mr. Furneaux Jordan, on account of pain and intestinal obstruction, but as this was found to be incomplete and intermittent, the abdomen was not opened. Large masses of growth could be felt in the pelvis and omentum; these rapidly increased and she died on September 7th, three weeks after her readmission, that is, within three and a half months of the ovariectomy. The section, which was prepared by Dr. Smallwood Savage, showed that the tumours were glandular carcinoma.

(2) A large, many-lobed myomatous uterus successfully removed by supravaginal hysterectomy. The patient was a small, thin woman, *æt.* 42, and the operation had been performed on account of pain, symptoms of pressure on the bladder and bowels, and enlargement of the growth. The lobular masses ran under the peritoneum in several directions and were enucleated from their beds. The peritoneum and floor of the pelvis were injured to such an extent that the abdominal cavity could not be closed by a complete transverse suture, and as the extensive opening up had led to free oozing, Dr. Edge thought it better to open the vagina and drain. During the following night there was sudden and very severe hæmorrhage, and it seemed that he would have to reopen the abdomen. Fortunately the bleeding ceased and did not recur, and there was no other disturbing symptom. Though there had been such extensive laceration of the tissues, there was no fever, and this absence of reaction after such severe surgical wounds he attributed to the use of antiseptically impregnated sutures and the prevention of the so-called "implantation infection" more than to any other factor. His silk sutures are boiled in solution of corrosive sublimate or of biniodide of mercury, and used straight out of the solution; silkworm-gut is treated in the same way; catgut is boiled in xylol, preserved in alcohol and corrosive sublimate (1 : 1,000) and used out of the preserving medium. Even if the outer surface of the ligature or suture be soiled by the hand, the antiseptic material is afterwards given off by them and kills the germs or inhibits their infective action until the normal currents are re-established and the phagocytic agents are able to destroy the micro-organisms.

Mrs. SCHARLIEB mentioned a case similar to the one first related by Dr. Edge. She removed two solid malignant ovarian growths with thin, ordinary pedicles, and had no reason to suppose that the operation was in any way incomplete, but the woman died about six months later from a secondary growth affecting the transverse colon.

Mr. FURNEAUX JORDAN said that when, in the absence of Dr. Edge, he was called to the case, he expected to have to operate for intestinal obstruction, but by the aid of injections the bowels were freely relieved and he could then feel a small lump behind the cervix. As the only history he had was that the tumour removed was a solid ovarian one, and he had no hint of its malignant nature, and as the obstruction had been relieved, he did not interfere, and in a few days was glad he had abstained from doing so, for in those few days the growth had increased so rapidly in size that it rose right out of the pelvis and could be felt in the abdominal wall.

Dr. EDGE said that it would have been natural for Mr. Jordan to suppose that after such a recent operation the obstruction was due to intestinal adhesion to the stump or pedicle. A fatal termination from the

recurrence of such a malignant growth within three and a half months after a complete operation had not, so far as he knew, been previously recorded.

Mr. J. FURNEAUX JORDAN showed:—

1. *Double Tuberculous Pyosalpinx*.—A. H., *æt.* 21, single; general health good. For some four months had indefinite pain in the lower part of the abdomen, but did not think it was anything serious. One day, when having her bath, felt a lump in the lower left part of the abdomen. The pain becoming worse, she went to her doctor, who asked me to see her. On examining her I could feel the top of two distinct swellings above the pelvic brim. Since, apart from the pain, she complained of nothing and there was no interference with her general good health, I thought it was an ovarian cyst. It was two or three weeks before I could admit her into the Women's Hospital, and by that time the pain had become very severe. On April 19th last I removed by abdominal section the two tubes you see here, the larger one from the right side. A few tubercles were dotted about the peritoneum of the broad ligament. One ovary, quite free from tubercle, I left alone; the other I removed. The patient now, six months after the operation, is in excellent health.

2. *Cystoma of Left Ovary*.—Mrs. H., *æt.* 28, was four months pregnant and complained of excessively frequent micturition and constant bearing down pain. On examination I found the uterus pushed up into the abdomen and the pelvis completely filled by a tense, elastic tumour. On May 8th last, I operated at the Midland Nursing Home by the vaginal route, and through a small incision into Douglas's pouch I tapped the cyst, pulled it out, and ligatured the pedicle. The cyst was a good bit larger than it appears to be, the walls being stretched and thinned. Fortunately there were no adhesions. Pregnancy was uninterrupted.

Mr. JORDAN said that he was not now so keen on the vaginal route for operating as formerly; but this case of the removal of a cystoma from a pregnant woman without any interruption of the pregnancy showed that there were cases in which the vaginal way had very great advantages and should certainly be chosen.

Dr. WILLIAM DUNCAN said that tuberculous pyosalpinx was met with in some women who appeared to be the picture of health, and it was remarkable how well such cases did even though, at the time of the operation, they might seem to be most unfavourable, and the whole of the peritoneum might be studded with millet-seed tubercle. He instanced a case in his own practice which afforded a typical specimen of double tuberculous pyosalpinx, now in the museum of the Middlesex Hospital, both tubes being distended with cheesy pus. Five years after the operation the patient was in perfect health. Tumours complicating pregnancy were always of very great interest, and when ovarian should invariably be removed at whatever period of the pregnancy they might be detected. But he must join issue with Mr. Jordan as to the vaginal route, for he thought the abdominal route should always be chosen. He would be sorry to open the vaginal vault, hoping, but by no means sure, that there were not adhesions that might make the removal of the tumour difficult or impossible. As a good example of the superiority of the abdominal route and of the tolerance of the womb, even during labour, to surgical proceedings, he mentioned that in a young married woman in whom a contracted pelvis was suspected, he found not only a pelvis *justo minor*, but a hard tumour fixed to the sacrum, which would have prevented delivery by the natural way. At term, labour having begun, he opened the abdomen, and determined to try and remove the tumour before deciding to open the womb; he extended the incision to the ensiform cartilage, drew out the uterus, and was then able, with much difficulty, to remove the sacral tumour, a dermoid. He returned the uterus to the abdomen and closed the wound at ten in the morning; the patient was delivered by forceps at two o'clock

the same afternoon, and made a perfect recovery without any rise of temperature.

Dr. MACNAUGHTON-JONES said that it was not uncommon to have absence of pain in pyosalpinx, and instanced some cases in which this immunity was present, notably one he had recorded at the Obstetrical Society, in which there was a large double pyosalpinx. The pelvis was filled by a large effusion containing two pus sacs, and the bladder was distended from pressure. The patient had never complained of pain, and the symptom for which she sought relief was incontinence of urine. He had brought a case of tuberculous salpingitis before the Society three years ago, which was unilateral, and the sac similar to one of those shown by Mr. Jordan. It was primary tuberculosis, and the lady had since had two pregnancies, one of which was a twin birth. The lesson to be learned from these cases was that the risk entailed by the non-removal of such pus sacs was very serious. As to the second specimen, the choice of operation for ovarian cystoma by the vagina would depend upon the diagnosis, the unilocular nature of the cyst, and the absence of adhesions. Given accuracy of diagnosis on these points, there could be then no doubt that the vaginal route would be the preferable one, but such diagnosis was sometimes extremely difficult. Operation on ovarian cystoma in pregnancy was now the accepted rule, but the time of selection was from the end of the second to the fourth month.

Dr. BEDFORD FENWICK said that the case of tuberculous tubes shown by Mr. Jordan was one in which he felt the greatest interest because, apart from the excellent results obtained by Mr. Jordan, the case opened up a very large and important question. He had operated on a considerable number of these patients, and with results which had more and more impressed him with the advisability of early operation in all cases of pelvic disease which appeared to be tuberculous in character. Most abdominal surgeons had met with cases of tuberculous peritonitis in which the mere opening of the peritoneal cavity, even if nothing else was done, had been followed by the disappearance of the peritoneal mischief and more or less rapid improvement in the patient's health. But it almost appeared as if the logical lesson of that fact had not been entirely appreciated; his experience compelled him to believe that there were a large number of cases of tuberculous disease in women, which originated in the ovaries or tubes; and that the early removal of the primary disease, even if secondary mischief had appeared, must be productive of some good, and might even lead to cure. At any rate, he had seen a number of cases in which the latter event had occurred, and might mention one excellent illustration of it. A woman, *æt.* about 33, had been admitted into his wards for ovarian and tubal disease and general peritonitis. It was evidently tuberculous in character, and the apices of both lungs contained cavities, whilst the patient was reduced to a state of extreme emaciation and exhaustion. Before operating, he pointed out that his hope in these cases was by removing the original source of disease to prevent further general infection, and certainly to cure the tuberculous peritonitis, and assist the patient in fighting against the pulmonary extension. In that case, both ovaries and tubes were found to be extremely diseased, and the whole pelvic contents matted together, whilst the intestines and peritoneum were thickly studded with miliary tubercles. He removed the diseased appendages. The peritonitis completely cleared up, the lungs commenced to improve at once, and when she left the hospital she had gained more than a stone in weight, and the pulmonary cavities were healing. Some months afterwards, when she reported herself, her general condition was excellent in every way. It was almost needless to say that equally good results could not always be obtained. When, for example, the lumbar or thoracic glands had become infiltrated, so that secondary foci of infection had developed, one could not hope for complete cure, but as it must take

some time for secondary developments, he was convinced that early operation afforded the best ground for hope that a complete cure might be effected, and that it was not only common sense and surgical science in these, as in every other case, to remove as speedily as possible the *fons et origo mali*, but that, in these cases of tuberculous pelvic disease, there was a great possibility, by early operation, not only of removing the local disease from which the patient suffered, but also of saving her from the gravest secondary developments.

Dr. E. TENNISON COLLINS agreed with Dr. Macnaughton-Jones that if in diagnosis one could be sure that the cyst was unilocular and non-adherent, operating by the vaginal route was both simple and rapid. He recalled two cases of his own, in one the cyst was large, and in the other, though not so, it was rapidly increasing in size; in each case he opened the abdomen by a small incision, both went on to term, and did well. As it turned out there were no adhesions in either case. He was glad to hear Dr. Duncan speak so emphatically in favour of the abdominal route.

Dr. EDGE remarked that though much of his experience accorded with that of Dr. Bedford Fenwick, he could not be so enthusiastic about the effect of removing tuberculous appendages upon tuberculous lesions already present in the lungs. On the whole the results of his operations had been favourable, but by no means so brilliant as described that evening. For instance, after an operation of the kind last summer, the wound healed well, and all seemed satisfactory for a fortnight, when, suddenly, the patient's mental condition changed, miliary tuberculosis set in, and she died in a fortnight. There was, it is true, an abscess cavity in the lung.

The PRESIDENT said that he entirely agreed with Dr. Edge. Nor very long ago, after a difficult operation for the removal of a tuberculous pyosalpinx, he obtained a comparatively good result for two or three weeks, but the patient afterwards succumbed to tuberculous meningitis. With regard to operating by the vaginal route in pregnancy: A tumour in pregnancy which gave distinct evidence of fluctuation, and of being a cyst, and not a dermoid, was very rarely adherent; and it was infinitely better to attack it by the vagina, especially if the cyst was blocking the pelvis below the pregnancy. In a case very similar to Mr. Jordan's, which he brought before the Obstetrical Society some years ago, the operation was a small one, the cyst could be quite easily removed, there was no abdominal wound, and the pregnancy was not interfered with at all. In such cases he considered the vaginal route ideal.

Mr. FURNEAUX JORDAN, in reply, said that the President had to a great extent answered all that had been advanced against operating by the vagina. Dr. Duncan, however, seemed to think that if the cyst had been adherent he (Mr. Jordan) would have been in a serious difficulty, and in this he could not agree. He could have proceeded at once to operate from the abdomen and the patient would have been none the worse for the small opening that had been made in the vaginal vault. The case was an excellent illustration of the fact that, as the President had said, when there were no adhesions and the tumour was below the pregnancy, the vaginal route was the right one. To say or infer that he would adopt the vaginal route in every case would be absurd. The President and Dr. Edge had also answered some of the remarks that had been made as to the effects of operations for pelvic tuberculosis. The benefit upon tuberculous peritonitis of merely opening the abdomen was well known, but, as regards the wider operation for the removal of tuberculous pyosalpinx, it was most difficult to give any prognosis, especially where there was general peritonitis and extensive deposits in the mesentery. One case would get well and perhaps the next, apparently quite similar, would not. One could not say why, but only hope for success knowing the best had been done.

Dr. WILLIAM DUNCAN showed a specimen of cancer

of the body of the uterus, and read notes of the case, which will be found on page 434.

Mr. BOWREMAN JESSETT did not understand why a combined vaginal and abdominal operation should have been required; a uterus of the size shown was, in his opinion, comparatively easy to remove by the vagina. Of course, in very fat women there was more difficulty, but that could be overcome by making a deep incision on one or even both sides of the rectum through the perineum and para-vaginal tissue, extending to the fornix. He had practised this method for several years, and believed he adopted it before it came to be known on the Continent as Schuchardt's incision.

Dr. HEYWOOD SMITH said that in the hands of one accustomed to use it the sound would give information of any tortuosity of the canal or roughness of the internal surface of the uterus; if it were possible to diagnose malignant disease in that way it might be better to remove the uterus at once without curetting.

Dr. F. A. PURCELL said that at the Cancer Hospital, where they had to remove many uteri, they had found that in a patient such as Dr. Duncan had described, the abdominal route was practically out of the question. With the aid of the incisions Mr. Jessett had described, and which Mr. Jessett and he himself had developed independently, ample room could be got to secure the broad ligaments and bring down the uterus.

Dr. MACNAUGHTON-JONES said that he could not agree with Dr. Purcell's remarks as to the removal by the abdominal route being out of the question in any case of uterine cancer. Wertheim, v. Rosthorn, and a considerable proportion of the most distinguished gynaecologists operated by the abdomen in all cases, though a large number of men of equally high reputation thought the best results were to be hoped for from early vaginal extirpation. The contrast in practice had been well reviewed by Olshausen, at Oxford, quite recently.

Mr. CHARLES RYALL said that in some cases in which vaginal hysterectomy seemed almost impossible, it was found that the abdominal operation was not any easier. For the patient's sake, the best operation was the quickest, and where time was the object he would pull down the uterus, and having opened the anterior and posterior fornices, would split it, and, to avoid the loss of half an hour in trying to get ligatures on the broad ligaments, would apply forceps.

Dr. J. J. MACAN asked whether anyone would now seriously advocate the bisection of the body of a cancerous uterus.

Dr. HERBERT SNOW asked for the grounds upon which Dr. Duncan had based his diagnosis, and what were the clinical symptoms. He thought the use of the sound unnecessary and undesirable for the diagnosis of uterine cancer.

Dr. EDGE asked Dr. Duncan what degree of elevation he was able to obtain. It seemed hardly possible for any woman to be so stout that, with full elevation and complete retraction, one would not have a better attack on the fundus from the abdomen than by any vaginal route.

Dr. DUNCAN, in reply, pointed out that he had laid much stress upon the extreme narrowness of the vagina of this patient as the reason in the first place why he had not undertaken a vaginal operation, which he agreed with Mr. Jessett to be the way of best attacking a cancerous uterus. In answer to Dr. Snow, he said that he used the sound because, owing to the woman's obesity, it was impossible to ascertain the size of her womb by bimanual palpation. There were no clinical symptoms pointing to malignant disease, but as he had mentioned, Mr. Targett had made a report upon the microscopical examination of scrapings from the cavity, and he had no doubt as to the diagnosis. He hardly ever made use of the sound, either for diagnosis or treatment, and naturally would not have done so had he had reason to suppose that there was cancer of the fundus. Time was no doubt most important, and more than an hour taken over an abdominal operation certainly militated against the patient's

recovery, but, as long as the time did not exceed an hour, he thought it did not much matter. He felt sure that Mr. Ryall would not advocate the bisection of a cancerous uterus if he had had the same unfortunate results from forceps that had occurred to himself, and would give up forceps in favour of ligatures. Replying to Dr. Edge: He was not able to obtain satisfactory elevation as the operation took place at the patient's house, and no table suitable for the Trendelenberg position was to be had.

Mr. RYALL said that he would prefer bisecting even a cancerous uterus to leaving it behind unremoved. With regard to Dr. Duncan's remarks about forceps: these, when applied to blood-vessels, did not act like a string tied round an indiarubber water tube, but, by causing stasis, led to the coagulation of the blood in the vessels, and when coagulation had occurred there was no reason, if ordinary care was employed, why they might not be taken off without any hæmorrhage. They had been successfully used by gynaecologists in thousands of cases.

Dr. MACNAUGHTON-JONES showed "Two Microscopic Sections": the first from a Case of Hystero-salpingo-oöphorectomy for Hæmorrhagic Endometritis due to Glandular Endometritis, and said that the case was interesting more from a clinical and pathological than from an operative point of view. The differentiation of the various forms of hæmorrhagic endometritis included therein was another matter, and a most difficult one. He hoped on a future occasion to indicate the histological differentiation of the various forms of endometritis which lead up to what is called hæmorrhagic endometritis. In addition to the specimen shown there was another on the table which he had shown at the Society before; he had brought that uterus and adnexa that it might be compared with his own specimen. Here the adnexa of one side had been first removed, and subsequently those of the other, for cystic disease; finally, the uterus, for hæmorrhagic endometritis. The patient was now perfectly well. The pathological report was that the adenomatous change was extending from the endometrium into the substance of the uterus. In the case now before the Society for the first time, the patient, who consulted him in November, 1902, was in her 43rd year, and was over six feet in height. She had cardiac complications, and was completely blanched from constant hæmorrhage. After a month's rest she was curetted, and the report stated that there was nothing malignant, and only some slight glandular changes in the endometrium. Her health improved, and the hæmorrhage ceased for a time. It recurred later, and she consulted him again in April of the present year. She was again curetted. The report then furnished to him by Dr. Cuthbert Lockyer was that the endometrium presented large round-celled infiltration of the stroma, the tubules having in many instances become distended into small cysts. A few of these were large enough to be distinguished by the naked eye. The curettings were under the microscope, and the changes described by Dr. Lockyer were quite evident. After a brief respite, the patient again suffered from recurrence of the hæmorrhage, and in August he performed complete salpingo-oöphorectomy, from which she completely recovered. There was an interesting point with regard to the specimen. After removing the uterus he split and cut up either cornu in the usual fashion, and out of one exuded what appeared to be pus, to the extent of about one and a half teaspoonfuls. He thought it was a case of suppurating endometritis, but a further examination showed that it was not pus. An abstract of the histological report is of interest:—The uterus has been slit open towards the left cornu, as directed, and sections cut in this situation. They reveal a healthy fibro-muscular wall, but a thickened endometrium covered by a pultaceous deposit consisting of epithelial debris. The endometrium shows two pathological changes, advancing *pari passu*, viz.: interstitial fibrosis and desquamation of the gland tubules, both changes being well marked.

There was no sign of an abscess cavity. The extreme desquamation of the glands amply accounts for the mass of shed epithelium and *débris*, which looked not unlike true pus. The wall of the uterus at its thickest part measures one inch. There is a small circular fibroid the size of a marble in the left uterine wall, just above the line of amputation. The right ovary was cystic the left also; two small blood cysts and both tubes showed evidence of chronic salpingitis.

The second was a rather unique specimen, which he had brought from Bonn that week, from Professor Schroeder, assistant to Professor Fritsch, of that University. It was the section of an ovary from a still-born child dying in birth, and showed typical commencing ovarian cystoma.

Owing to the lateness of the hour these specimens were not discussed.

Mr. CHRISTOPHER MARTIN then read a paper on "The Treatment of Severe Prolapse by Extirpation of the Uterus and Vagina," which will be found on page 429.

The discussion of this paper was postponed.

PARIS, October 23rd, 1904.

#### TREATMENT OF ARTERIO-SCLEROSIS.

THE name of arterio-sclerosis is given, says Dr. Debrive, to a chronic affection of the small arteries, whose walls are invaded by sclerous tissue. These lesions are habitually generalised and attack the arterioles of the viscera—liver, kidneys, brain, heart, &c.—producing in those organs anatomical and functional troubles, giving to the disease its particular character.

The cause of arterio-sclerosis is very varied—arthritis, gout, chronic rheumatism, obesity, diabetes. Besides these, certain infectious maladies, as typhoid fever, syphilis, paludism, &c., can modify the arterial walls by their effect on the blood and produce sclerosis in time. Slow and prolonged poisoning of the blood is one of the most powerful factors in the production of the disease. Saturnism, smoking, and alcoholism have been incriminated. The same may be said of physical and mental strain (*surmenage*).

Besides these etiological conditions, age, with the progressive waste of the tissues resulting from the wear and tear of the organism and the incomplete elimination of the waste, is capable of producing alone arterio-sclerosis. Very few aged persons or even younger adults are exempt. The male sex is much more frequently attacked than the female sex; and heredity plays a certain *role*. For Professor Huchard the mode of action of the causes of arterio-sclerosis is arterial hypertension gradually provoking vascular irritation, ending in sclerosis. The internal tunic of the small arteries is thickened, with tendency to obliteration, and the troubles of the circulation resulting from the lesions can provoke gangrene or necrosis.

In its initial period, arterio-sclerosis presents no signs of precise location. The patient complains of manifold troubles, dyspnoea in walking, or on slight efforts, accompanied by a disagreeable sensation of constriction in the thorax. The digestion is laborious; after the repast, the face, generally pale, becomes coloured, and at the same time he complains of palpitations and a tendency to sleep. The temporal arteries generally regular, pulsate violently. The pulse is regular but rather strong (and rapid; the arteries are hard. Auscultation of the heart reveals a loud dyostatic sound at the aortic orifice, the other sounds are also sharp and regular; the organ is generally hypertrophied. The urine is abundant and limp.

Such are the symptoms of arterio-sclerosis at its commencement. Progressively these different manifestations of the malady finish by predominating in a vascular territory. Of all the organs, the kidney is the most frequently affected, after which comes the heart, and finally the brain.

The renal type of arterio-sclerosis develops insidiously without any other manifestation than that of arterial hypertension. It is characterised anatomically by interstitial nephritis. Clinically, polyuria is observed, slight albuminuria, palpitations with a *bruit de galop*. Patients affected with arterio-sclerosis succumb frequently to nephritis, heart disease, hæmorrhage, or softening of the brain. Consequently the prognosis is generally grave, although it varies with each particular case; renal or cardiac insufficiency renders it very sombre.

#### THE TREATMENT OF ARTERIO-SCLEROSIS.

The treatment consists of two parts: hygienic and medical. The quantity of aliments should be reduced to a simple sufficiency. Meat, the principal cause of alimentary intoxication, should be consumed with the greatest moderation. Game, pork, salt meats, should be proscribed, as well as fish, preserved meat, asparagus, tomatoes, mushrooms. Milk should be the exclusive diet where the patient complains of oppression, headache or insomnia. As regards liquids, water is the best, but a little white wine well diluted with water may be given at meals if the patient desires it. The only therapeutic agent which appears to act beneficially in retarding the evolution of arterio-sclerosis is iodide of potassium. It should be given in small doses, from 5 to 10 grains, daily for a long time, twenty days a month; and continued for a year or more. Trinitrin is recommended where dyspnoea or vertigo exists, in the dose of 2 drops morning and evening of the 1 per cent. solution. As soon as the heart gives signs of weakness, strophanthus or spartein may be ordered, but digitalis is counter-indicated as long as hypertension exists; it will be reserved for the period of œdema.

Trunczek, of Prague, has invented a serum, of which the following is the composition, to supply the salts wanting in the blood in arterio-sclerosis, and which seems to have given some good results in the initial period:—

Sulphate of soda, 0'44 centigr.;  
Chloride of sodium, 4'92 centigr.;  
Phosphate of soda, 0'15 centigr.;  
Carbonate of soda, 0'21 centigr.;  
Sulphate of potash, 0'40 centigr.;  
Water, 100 grammes.

He injects under the skin from 1 to 7 centimetre cubes.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 22nd, 1904.

#### FURTHER DISCUSSION ON LIGHT TREATMENTS.

At the International Dermatological Congress, Hr. Freund (Vienna) reported his experiments, in conjunction with Oppenheim, as to measuring the action of the Röntgen rays. Gaucher and Werther had seen inflammation of the kidneys after Röntgen treatment. Buschki and Schmidt (Berlin) had come to the following conclusions: (1) It was possible to cause deeper layers of epithelium to disappear without severe changes in the overlying skin. (2) Necrosis and also molecular destruction in the sense of simple atrophy could be wrought about in the epithelium of glandular organs by the Röntgen rays. (3) Under suitable conditions

change or a suppression of function in a gland could be brought about by them without any grave anatomical changes.

Hr. Schlotz (Königsberg) related the results of his experiments on the action of concentrated lights. The action of the Finzen light, he said, did not depend alone on the action of the very frangible ultra-violet and blue-violet rays, which by their absorption brought about actual chemical action (chemically active rays), but also on the action of the lesser frangible rays, which caused warmth by their absorption. A portion of the chemically active rays might even penetrate deeper layers of tissue; the physiological effect of these rays was but small, however. The physiological action of these chemically active rays diminished rapidly, therefore, in the deeper tissues. The heat rays had a greater penetrating power, and their action on the superficial layers could be governed at will by cooling apparatus. It might easily be that the effect of the heat rays as regarded deeper structures did not diminish, but, on the contrary, increased. The intensity of the action of light rays on the different parts of the skin naturally depended on the rate of absorption, and as the diseased tissues of lupus were darker in colour than the normal skin, and in consequence of this the rate of absorption would be greater in the diseased than in the normal tissue, so the rays of light would act electively on the lupoid tissues. On this probably depended the favourable action of light in the treatment of lupus. The action of the whole of the light rays might be heightened by suitable colouring of the deeper layers of skin, but the procedure of colouring would be of little use in the case of lupus as the light already acted electively.

In a discussion on radium treatment, the same speaker summarised his conclusions as follows:—The physiological action of the rays from radium on the whole resembled that from the Röntgen rays. It differed from it, however, in the following: The radium rays had a greater effect on the vessels; they had a more powerful, deep action, and they had a not inconsiderable bactericidal action. From a therapeutical point of view the action of the radium rays was, on the whole, similar to that of the Röntgen rays. The action of the radium rays was more energetic than that of the Röntgen rays in the following: The radium rays acted more powerfully and more favourably in malignant new growths of the skin, especially carcinomata. The radium rays acted better in telangiectases and small angiomas. Above all, the radium rays could easily be applied in many parts of the body, and especially in cavities, where the Röntgen rays could not be applied.

The *Deutsch med. Zeitung*, No. 77, has a reference to the case in which a

#### CROQUET BALL WAS RETAINED IN THE VAGINA FOR YEARS.

The patient was a country-woman, æt. 60, who complained of pain in the lower part of the abdomen and in the vagina, also of shortness of breath, cough, and a purulent vaginal discharge. She had been married 48 years, had borne two children, the first 34 years ago, and the second a year and a half later. The menses began at 20, and recurred at four weeks' interval, lasting five to seven days. After heavy work the patient felt the womb falling. She applied to a midwife, who, however, gave her no assistance, and in consequence of this she herself attempted to get relief by inserting various objects into the vagina. After the birth of the second child the womb fell further still, and she passed a croquet ball into the vagina. After that

she had no more symptoms of falling of the womb nor any pains, and the functions of both bowel and bladder were performed normally. On examining *per vaginam*, the introitus was found to be very much contracted, and behind the introitus the finger came upon a round, hard body. A muco-purulent discharge issued from the vagina. The urethra was of normal calibre, and clear urine was passed; neither was the rectum unduly pressed upon. The rounded foreign body was lying loose in the vagina, it could be grasped with forceps and moved freely. On account of the great narrowing of the vagina below, however, it was impossible to remove the ball entire; it had, therefore, to be broken up with a strong pair of forceps. The wood of the ball was unchanged; it was still fresh and firm. There was severe colpitis, and in places superficial ulcers were present. Patient discharged on the fifth day. The uterus was then small and atrophied, and in the vagina where the ball had been there was a ring-shaped contraction. There had been no perforation. There was no pain.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 23rd, 1904.

#### RECURRING ULCUS VENTRICULI PEPTICUM.

At the Prague meeting Schloffer showed a very interesting case of recurring ulceration of the stomach for which he had to perform gastro-enterostomy five times within two and a half years. The patient, æt. 33, had again developed the same condition of ulceration, and stenosis at the site of operation, which would again necessitate laparotomy.

#### TUBERCULIN REACTION.

Zupnik read an exhaustive paper to the members on the classification and reaction of bacteria. Commencing with their analogy to plant life he attempted to group them according to species and genera, into what he terms a natural system having well-defined marks of distinction. His whole system was established on morphology-colouring and pathological properties of the bacteria. As an example of these he selected Koch's acid-colouring species, which were known as the tuberculin bacilli. Their morphology was by true division with a Babes-Ernst body in the interior of the germ. A culture in clear bouillon gives a characteristic surface and its pathology produces tubercle. This family seem to give rise to different products; for example, he would quote twelve experiments on guinea-pigs with the different forms of Koch's species; six of them reacted with injections of Höchster's tuberculinum vetus as positive. This family appears to be closely connected with the harzstreptothrix, as tuberculin injections will react positively on lepra actinomycosis as well as tuberculosis, although in several experiments four different forms of streptothrix were found. From this and other experiments Zupnik concluded that the tuberculin reaction gave no diagnostic proof of this particular bacteria, although it defined the species.

The same reasoning was applied to typhus and paratyphus serum, which did not define the particular bacilli, but only the species of typhus bacilli, which might include the dysenteric, psittacosis, typhimurium and enteritidis, as well as the coli family. These again were subdivided by the agglutination phenomenon or the Gruber-Widal action, which could not be held as a specific etiological test. Again, these species of bacteria produce pathological changes which clinically and anatomically resemble each other, such as lepra

tuberculosis and Peru verruga, all resembling each other in having the tuberculous bacillus. He also recorded another clinical disease of the kidney which had its origin from Koch's bacillus, though apparently belonging to another tuberculous family which he would designate the smegma bacillus. In the discussion, Salus said that the family of tuberculous bacilli produced a chemical constituent which was not affected by the acid, and the same product could also be extracted from the bacillus itself. He believed there were different bacteria belonging to the same species producing similar metamorphoses and the same disease. He thought the experiments with the smegma bacillus did not prove the presence of tubercle owing to the absence of caseation, which did not exist, and which genuine tubercle always produced when inoculated. The tubercles alone were not characteristic, and required the caseation as proof. He admitted that different toxic substances could be extracted from the bacillus, many of which were specific, such as tuberculin, which had no characteristic phenomenon in the production of tuberculosis, and had no immunising power on animals. Zupnik replied that caseation in Koch's bacillus was neither characteristic nor proof of its genuineness as streptothrix and Pfeiffer's pseudo tuberculous bacilli all produced cheesy conditions in the tissues. As to the nephritic tuberculosis the diagnosis was the same in all bacteriological examinations, while the urine drawn from the ureter gave the same result, such as acid reaction, numerous leucocytes taking up acid colouring matter having genuine Koch's bacilli. In forty guinea-pigs which were inoculated with pure cultivated Koch's bacilli only the smegma bacilli were found.

#### FISTULA OF BLADDER AND BOWEL.

Kleinhaus showed a female, *æt.* 47, who had been confined sixteen times, and suffered from a fistula passing from the bladder into the bowel. The uterus and adnexa were normal, as well as the tissue around the cervix and fistula. He assumed that this condition was produced by an attack of perivaginitis phlegmonosa dessicans described by Marcomiet in 1865. This appears to have been induced by puerperal infection and injuries during delivery. It is possible to assume that infectious thrombi in the vessels of the vagina and portio were the starting point of the inflammations.

### The Operating Theatres.

#### NORTH-WEST LONDON HOSPITAL.

TWO CASES OF INTERMITTENT NASAL OBSTRUCTION WITH HYDRORRHOEA.—Mr. MAYO COLLIER operated on two cases of intermittent nasal occlusion with hydrorrhœa. The first case was that of a man, *æt.* 50, who had suffered for the last twenty-seven years from sudden, almost complete nasal occlusion associated with an outpouring of a large quantity of clear fluid. The attacks were so sudden that from a condition of complete and perfect nasal respiration the occlusion would suddenly come on, rendering the patient utterly miserable and quite unfit to continue his work for several hours to come. He stated that he had been examined and operated upon on several previous occasions with only slight temporary benefit. He had been advised to give up all alcohol and tobacco and undergo a course of medicine and dieting. This he had done religiously without apparently any benefit. Mr. Collier described the condition of the nose on admission. The whole mucous membrane was intensely red and

congested, there was much hypertrophic thickening of the lower turbinal body, culminating posteriorly in a left posterior hypertrophy, which almost completely occluded the posterior nasal opening. There was a fringe of thickening hanging from the middle turbinal body of almost polypoid consistence. On the right side there was a large ridge involving the right nasal cavity and touching the right lower turbinal body. Mr. Collier said two previous operations had been done in this case with the object of removing the posterior hypertrophy on the left side and reducing the lower turbinal body. These operations had resulted in considerable improvement, so much that the intermittent nasal obstruction on the left side had completely disappeared, and the discharge had been reduced considerably. He said he proposed now to remove the whole of the ridge on the right side so as to restore nasal respiration. The patient was anaesthetised with chloroform and placed in a semi-recumbent position on his left side. Mr. Collier made an incision along the lower aspect of the ridge with a scalpel, and introduced a fine Bosworth's saw. After considerable trouble (the ridge being very hard), the parts were sawn through and removed entire with forceps. Some subsequent chiselling had to be resorted to in order to complete the operation. Mr. Collier next demonstrated the complete freedom now obtained, by introducing a large piece of sponge on artery forceps, which now passed easily from front to back. There was considerable hæmorrhage during the operation, which, he said, would rapidly subside as the air passed backwards and forwards. No plugging or dressing was resorted to, but the patient was returned to bed. Mr. Collier said that in these cases no plugging was requisite, the air quickly arresting the bleeding and leaving a dry clot on the wounded surface.

The second case was that of a young man, *æt.* 24, who had suffered very much for several years from almost a similar condition as that seen in the previous case. The condition of the nasal cavities in the present case was one of marked lower turbinal hypertrophy with anterior and posterior enlargements. The attacks of sudden occlusion were so severe that the patient had been quite unable to follow his occupation from want of rest at night and generally impaired health. Mr. Collier said that in this case he had previously removed the two anterior hypertrophies and reduced the turbinal bodies on both sides with the galvano-cautery. He now proposed to remove the posterior hypertrophies with a cold snare. Twenty per cent. solution of cocaine with adrenal was placed on both hypertrophies, and, with the aid of good light, Jarvis's snare was introduced, first on one and then on the other side, and a structure as large as a cherry removed by slowly tightening the loop on the masses. There was no hæmorrhage, and the parts were apparently bloodless. Mr. Collier said it was quite unsafe to leave the wound without plugs or using the galvano-cautery; he preferred the latter, as the former would leave the patient in a miserable condition, and the plugs would probably have to be renewed in twenty-four hours. If the galvano-cautery were carefully applied and the exact site of the wound could be seen, there was, he considered, no danger of injuring the Eustachian tube or pharynx. Mr. Collier carefully marked on the galvano-cautery instrument the exact depth of the wound and seared the cut surfaces on both sides with

the cautery point. With this precaution, he remarked, there was no danger of subsequent hæmorrhage, and the patient would enjoy immediate benefit of restored nasal respiration and the advantage of the astringent and drying effects of the currents of air.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 26, 1904.

### ST. BARTHOLOMEW'S REBUILDING.

THE affairs of St. Bartholomew's Hospital appear to have drifted more or less into the position usually described tersely as "a deadlock." That fact may be pretty safely inferred from the reported resignation of the Treasurer, Sir Trevor Lawrence, and the Secretary, Mr. Cross. Both these gentlemen have been strongly committed to the policy which involved the extension of the present site of the ancient City institution, and of rebuilding thereon at enormous cost. That policy has from the outset been vigorously opposed by THE MEDICAL PRESS AND CIRCULAR, and we have no hesitation in saying that our objections have never yet been satisfactorily answered. The formal inquiry into the question of the advisability of retaining the City site, held by the body known as "The Lord Mayor's Committee," was not of such a nature as to inspire confidence. Neither the composition nor the methods of that body seemed to us worthy of adoption in investigating a matter of great public and, indeed, national importance. The suspicion that the final resolution was simply an expression of dogmatic and personal opinion, rather than the verdict of an impartial tribunal, was rendered inevitable by the refusal of the Lord Mayor's Committee to publish the evidence placed at its disposal. The transaction, indeed, savoured rather of the tactics of company promoting than of the publicity and candour that should be courted by every self-respecting medical charity. If the reasons for retaining St. Bartho-

mew's Hospital on its present site were cogent and overwhelming, as the Lord Mayor's Committee led us to believe, what possible objection could there be to letting the public know the why and the wherefore of their belief? To withhold such information was to suggest that the Committee had a weak case, that they were acting under powerful personal pressure, that they dared not state both sides of the question; in short, that they were registering in their report a private prejudice and opinion in place of a reasoned verdict. Our own objections to the scheme were clearly and repeatedly stated. Coming from a medical journal, they were entitled to a detailed public reply. There is no need to reproduce them here at length. Briefly stated, we objected to the enormous cost of the scheme as a larger modern hospital could have been erected for a far less sum in the suburbs; secondly, the day population of the City of London no longer demanded a vast residential hospital, nor was it desirable to treat patients in the vitiated atmosphere of a vast city area; thirdly, the abstraction of a million of money, the amount required for reconstruction, would infallibly damage other deserving medical charities; lastly, there being every likelihood that the greater part of medical education would, in the near future, be centralised, the erection of costly school buildings would be thereby rendered superfluous. Remonstrance proved of no avail; the public was asked to subscribe £500,000, and it was determined to rebuild the hospital on the present site. The upshot, after an interval of nine months, has been what some of the daily newspapers do not hesitate to describe as a "fiasco." It is stated that the total sum contributed has been £35,000 in place of the £500,000 asked for by the hospital authorities, or the million that the completion of the reconstruction scheme will require. Already the hospital has drawn £150,000 from capital to pay for the purchase of the ground from Christ's Hospital needed for the extension of site. Indeed, it looks as if St. Bartholomew's had been plunged into a financial morass, from which it will tax the resources of another committee to extricate its fortunes. The governors of the hospital are even applying, in their extremity, to King Edward's Hospital Fund for assistance. The full significance of that fact becomes evident only when we recall the fact that Sir Savile Crossley, the Secretary of the King's Fund, was a member of the Lord Mayor's Committee who opposed the reconstruction report in a minority of one, and who afterwards withdrew from that committee. Now that Sir Trevor Lawrence has resigned his post as Treasurer of St. Bartholomew's, it may be possible to reopen the question. In that case it would be advisable to appoint a representative committee or Commission of Inquiry chosen from men of recognised standing and judgment not connected with the City. The suppressed evidence of the Lord Mayor's Committee could then be produced and laid before the public. It is difficult to

conceive how any body of educated men in the present day could advocate a hole-and-corner treatment of a question of universal public interest. The welfare of St. Bartholomew's Hospital must concern every medical man as it does every citizen in the United Kingdom. Let us thrash the matter out on that understanding in the full light of day.

#### SCIENTIFIC PALMISTRY.

PALMISTRY, as expounded by self-styled "professors" of the art, has been considerably to the fore during the last few months in consequence of the prosecutions that have been instituted in different parts of the country, to test the validity of taking money for telling people a farrago of nonsense about themselves, their past, and their future. Happily, the law has been able to show that there are certain occasions on which it is not "a ass," and the prisoners have been pretty generally convicted. The offence in law that cheiromants commit is that of predicting the future; the mere practice of palmistry is not illegal so long as it confines itself to the delineation of character, though the puzzle will always remain why people wish to be told what they should know better than anybody else, namely, their own qualities and shortcomings. However that may be, the subject of palmistry and its influence over the human mind is not without interest to the anatomist and the psychologist, and the study of the hand has important medico-legal bearings that are well worth attention. Palmistry itself as practised by its ordinary exponents, even when rigidly confined to the portrayal of character, is beneath contempt, for the study devoted by them to the subject is so little profound that in many of their treatises the lines of the hand and fingers are not even correctly described. A mass of crude astrology is mixed up with incorrect anatomical detail, and the traditions of the sixteenth century are eagerly copied from one book to another; however, enough meretricious nonsense results to attract silly people to resort to the authors for advice. Piteable as this is, there is an idea abroad with regard to cheiromancy that there is "something in it," and it cannot be denied that, though scientific palmistry has yet to be developed, the hand is, or ought to be, a useful guide to a man's character and habits. The hand is admittedly the most complex and perfect piece of mechanism ever conceived, and especially in the development and specialisation of its outer half, and belongs more intimately and peculiarly to man than any single organ, except the brain. The relation between the brain and the hand was insisted on by Aristotle; Anaxagoras ascribed the superiority of man's wisdom to the possession of the hand; Galen thought that because man was the most sagacious animal, he was endowed with the possession of hands; and recently the leading medical philosopher of the day, Professor Clifford Allbutt, deplored the abandonment of the hands as an educational instrument by modern and mediæval

physicians. The hand, in fact, in virtue not only of its tactile sensibility, but also of its muscular sense, is one of the chief sense-organs of the body, and it is certainly the chief exponent of the will. Its shape, its development, the texture of its skin, and the fashion of its fingers are determined by occupation and habit, operating on hereditarily-acquired characteristics and predisposition. The whorls on the skin covering the terminal phalanges of the thumb and fingers are now known to be peculiar to the individual, and M. Bertillon has shown how valuable they are for purposes of identification. As an expression of the personal character and habit the hand is only second in rank to, if not actually equal with, the face, and though the significance of physiognomy has been carried to undue extremes by some of its adherents, no one attempts to deny the part played by the face in the portrayal of the character and the emotions. The physiognomy of the hand, if it may be so termed, has been little studied by scientific observers—a great pity, as their place has been filled by charlatans and humbugs, who have taken the opportunity to fill their own pockets by the proceeds of their quackery. The foundations for a true science of palmistry have been laid by such works as Sir Charles Bell's classic book on the hand, and Sir George Humphry's writings on the same subject, while Dr. Warner, in his "Physical Expression," has carried the matter further by describing and figuring various types of hands pertaining to certain dispositions. The topic is one of extreme interest, and as there appears to be a demand on the part of the public to know about their hands, it may be hoped that a means of providing them with authentic information on the subject may be forthcoming. The only way to prevent them from having recourse to "professors" who read the hands for a guinea, or "madames" who do the same for a shilling at church bazaars, is, provide them with a trustworthy substitute. Scientific palmistry may not have so many wonders to reveal as old-time cheiromancy, but it would at least tell the truth. Every observant physician is something of a physiognomist, it would not detract from his reputation if he were able to elicit all that the patient's hand could tell him.

#### Notes on Current Topics.

##### The Midwives Act.

It seems unlikely that the Midwives Act in its present form will ever become popular with the medical profession. One of its radical defects is experienced in the oft-repeated assertion that it calls into being an inferior kind of unqualified medical practitioner. Another vital flaw is the absence of any financial arrangement as to the payment of medical men when called in by midwives to attend "difficult cases." Now that the views of the medical profession have been set aside in favour of sentimental legislation, Government will have to provide a fair remuneration for its expert services. The Medical Guild o

Manchester, an alert and practical body, have lost little time in coming to a conclusion as to what constitutes a right and proper recognition of the kind. At their last quarterly meeting they adopted the following resolution:—"That when medical practitioners choose to attend confinements at the request of midwives, the minimum fee charged should be a guinea, to be paid at the time when possible. This should be carried out for the present as a tentative arrangement till fresh legislation dealing with medical fees has been brought forward." Bad as the principles involved in this Bill appear to us, its administration bids fair to become infinitely worse. Already the Board that controls its destinies has appointed unqualified women to inspect and control purely medical matters. We regret that any members of the medical profession should be so forgetful of their duty, and their dignity, as to sanction any arrangement of the kind. Dr. Ward Cousins, who has throughout offered a determined opposition to this and to other steps derogatory to the interests of the profession, deserves the thanks of all his medical brethren. We trust that no medical man in the United Kingdom will accept a less fee than one guinea when called in by a midwife.

#### Fright, or Fear-Illness.

THE influence of the mind in producing disease is a subject that has fascinated various pens, but one cannot say that much light has been thrown on the extraordinarily delicate relationship that exists between mental processes and bodily illness. Ladies in novels, after their love troubles have been sufficiently elaborated, have a convenient habit of succumbing to the affection known as a "broken heart," and children, in the same class of literature, run a terrible risk of developing that equally obscure malady, brain-fever, when the writer feels it necessary to gather up the sympathies of the reader for a final crushing exposure of the brutality of the parents. Romance-literature, however crude it may be, always reflects experience in some form or another, and novelists who tread on delicate pathological ground have a certain basis of fact which is none the less real because it is overloaded. Army surgeons can tell many a story with closed doors—which they would not venture on in speeches at military dinners—about the effects of fear on the constitution of the raw recruit—"funkitis" as it was christened during the Boer War. That fear can produce severe and perhaps even permanent change in the mental and physical organisation has been shown often enough, and an interesting illustration in point is recorded in Lady Thompson's account in the *Cornhill Magazine* of her experiences in Kastoria, whilst distributing the Macedonian Relief Fund. This province had been ravaged by the Turks the previous summer, and Lady Thompson says that there was an illness, more or less serious and sometimes even fatal, peculiar to Macedonia, openly confessed to by the sufferers and known by the

doctors as *strach* (fear). The victims were not only those whose houses have been burned and relations killed, but many who had spent weeks and months in suspense, hiding in out-of-the-way corners of the mountains. They were often unable to walk and to speak, or even to stand upright, and yet organically they were sound and uninjured. Women seem to have been more affected than men, but both sexes suffered. The condition would appear to have been one of profound hysteria, such as is met with under some forms of mental distress, but this does not help us much to its actual pathology. The sufferers were thoroughly overcome with severe mental prostration, and it is doubtful if they will ever be the same as they were previously.

#### Professional Penalty for Extortion.

IT is not often that a medical society is called on to reprove one of its members for demanding a high fee for professional services, yet this is what has recently occurred in Germany. A physician of good standing, being consulted by an American millionaire for appendicitis, advised operation, and recommended a surgeon. The operation was performed, and the physician then sent in a bill for four hundred pounds for his advice. The patient objected to the amount and tendered a smaller fee. The physician, however, insisted, and initiating legal proceedings, had the patient arrested and kept in custody. There is, of course, no ethical law by which the fees of medical men are controlled, and it is well recognised that a physician is justified in varying his fee according to the means of the patient. There is, however, a decent though variable limit to the demands of a man honourable in his profession, and we think that his *confères* acted rightly in dissociating themselves from the physician in question when he attempted by legal means to put a foreigner at disadvantage for the recovery of an obviously extortionate fee.

#### A Paradise of Bonesetters.

RAE, the Scotch miner-bonesetter, is not to have things all his own way up at Blantyre. The railway trains still disgorge the lame, the halt, and the impotent in considerable crowds, attracted by the extravagant claims of his wonderful "system." Indeed, it is reported that cripples are coming from Germany, Sweden, Denmark, South Africa, and America to subject themselves to his manipulations, and altogether he seems to be having—as the schoolboys say—"a good time of it." But on the principle that competition is good for trade, two other "specialists" have set up in the neighbourhood so that they may enjoy the crumbs that fall from Rae's operating table. One of these individuals, Thomas Gilchrist by name, has indeed "gone one better" by announcing that he takes sciatica into his therapeutical province, and as Rae does not seem to be much of a hand at sciatica, patients having that trouble go on to Gilchrist. But dwellers south of the Tweed, to whom the pre-eminence of country is dear, will be

glad to hear that Scotland is not to go unchallenged for its supremacy in bonesetting, for another performer, an Englishman, named Fred Barker, is hastening to the scene, and is about to start in business midway between Rae at Blantyre and Gilchrist at Wishaw. Mr. Barker one would judge to be something of a capitalist, as he offers to pay £500 to any philanthropic institution if his system of manipulative surgery is not pronounced superior to, and productive of more benefit than, the scalpel of the local doctors. If, on the other hand, he comes off victor in the contest he is prepared to give £250 to found a school of bloodless surgery in Lanarkshire. With so many provincial universities coming into being, this new one (if founded) may make things uncomfortable, but we fear its handsome endowment will hardly succeed in retaining a professor unless he be also allowed the privilege of private practice in his wonderful arts. Altogether things seem very merry up in Lanarkshire, and Carlyle's quoted estimate of the British population does not seem likely to be falsified thereby in the near future.

#### The National Epileptic Colony.

ON Thursday last, October 20th, the Epileptic Colony at Chalfont St. Peter, in Buckinghamshire, conducted by the National Society for the Employment of Epileptics, marked an important stage in its rapid evolution by the opening of an excellently arranged and well-equipped administrative building, which, like so much in connection with the Colony, has been made possible by the judicious munificence of Mr. Passmore Edwards. The opening ceremony clearly indicated the keen interest taken by both profession and public in the rational and hygienic care of the epileptic. Lord and Lady Rothschild attended, and Sir William Broadbent and Dr. Buzzard took part in the proceedings, and Dr. Fletcher Beach, Dr. Shuttleworth, Dr. Aldren Turner, Dr. Kelynack, and others were present. Much praise is due to Mr. Nicholls, the chairman, for his wise pioneership in the development of the Colony. The new house contains offices, rooms for the staff, and a thoroughly modern and up-to-date kitchen. The various buildings which constitute the Colony are excellent for their purpose, and the whole conduct of the place appears to be characterised by scientific precision and sound common sense. There is much ground which allows of a free and open-air life and useful outdoor employment. This new but now large and flourishing Colony should be well known to medical men, who are so frequently called upon to advise regarding the protection and upbringing of epileptics.

#### The New President of the Royal College of Physicians, Ireland.

DR. W. J. SMYLY, who was elected President of the Royal College of Physicians of Ireland at its last meeting, is, as is well known, one of the most prominent of British gynaecologists. Dr. Smyly entered the medical profession through the portals of Dublin University in 1872. In 1877,

he became a Fellow of the Royal College of Surgeons, a distinction which he subsequently relinquished in order to take the Fellowship of the College of Physicians. In 1882, he was appointed gynaecologist to the City of Dublin Hospital, in succession to Dr. Arthur Macan, who has been elected to the vacant Mastership of the Rotunda Hospital. In the latter post, Dr. Smyly again succeeded Dr. Macan, and during the next seven years laid the foundation of his wide reputation. During his Mastership, the new gynaecological wing of the hospital was built, and many important reforms were introduced, notably nursing by trained nurses under a trained lady superintendent. So successful were these reforms that in the last year of his Mastership the mortality rate in the maternity department was reduced to the lowest that had ever been known in the hospital—only one death occurring amongst the 1,524 patients that were confined. On leaving the hospital, Dr. Smyly was appointed gynaecologist to the Adelaide Hospital, a post which he still holds. Amongst his other distinctions may be mentioned the Presidency of the British Gynaecological Associations and of the Obstetrical Section of the Royal Academy of Medicine in Ireland.

#### Venous Thrombosis in Typhoid Fever.

THE toxins elaborated by the *Bacillus typhosus* within the body are so insidious in their action, and so far-reaching in their effects, that no system can be said to be exempt from one or other complication or sequela. Modern pathological research has shown that the vascular system bears much of the brunt of the poison of typhoid fever, especially in the later stages of the disease. It has recently been found that evidences of functional and even organic disease of the heart may be traced to an antecedent attack of enteric fever, while arterio-sclerotic changes within the vessels have also been pointed out as a not infrequent sequel of this affection. That venous thrombosis is another complication likely to occur in the course of typhoid fever, or during convalescence therefrom, is shown by an analysis of forty-two cases of this condition made by Professor W. S. Thayer, (a) of Baltimore. Of these the left side was affected in twenty-six cases, while the femoral vein was thrombosed in twenty-one instances. The condition generally makes its appearance about the third week of the disease, but in some cases it may be considerably delayed. The onset is usually associated with sudden pain in the affected part, chills and fever. Some swelling of the thrombosed vein nearly always occurs, and there may be oedema of the adjacent integument. If the blood be examined at this period a leucocytosis will be found coincidently with the appearance of the thrombosis. In one fatal case the *B. typhosus* was obtained in pure culture from the thrombus. The after-results of venous thrombosis are important, as in almost all

(a) *Med. News*, October 1st, 1904.

the cases more or less permanent disability of the affected limb follows. Such symptoms as cramps, stiffness, and swelling of all the tissues of the leg were found several years after the attack. The risk of embolism is one which must, of course, be specially guarded against.

#### Baron Dimsdale.

BARON DIMSDALE, whose miniature-portrait has been so wantonly stolen from the National Portrait Gallery, lives in history as the medical man who received the largest fee for any single service. Born of Quaker parents in Essex, in the year 1712, and educated at St. Thomas's Hospital, he rapidly rose to fame as a physician, and became a Fellow of the Royal Society. It was in connection with inoculation for small-pox that he chiefly attained celebrity. This practice had been introduced into England by Lady Mary Montagu and others in the early part of the eighteenth century, and was widely practised till about 1740, when in consequence of many fatalities occurring among the inoculated, it fell into disfavour. Sutton, however, in 1763, announced a method by which he could assure that the resulting attack of small-pox should be mild, and he speedily gathered a large practice. Dimsdale modified the Suttonian method, and in his turn gained a wide connection, but though the matter had been frequently discussed, the so-called secret on which Sutton and Dimsdale built up their success has never been accurately determined. Dimsdale's peculiar luck came in his being summoned, in 1768, to Russia to inoculate the Empress Catherine and her son, the Grand Duke. Fortunately for him the operations were both successful, and he was rewarded with a fee of £10,000, an allowance of £2,000 for travelling expenses, an annuity of £500, and, as though pecuniary reward was not sufficient, was created Baron of the Russian Empire, Councillor of State, and Body Physician to the Empress. He returned to England, and soon afterwards was elected M.P. for Hertford, in which town he practised the combined callings of banker and physician. In 1781 Dimsdale was sent for to Russia again. This time he inoculated the Grand Duke, who was afterwards the Emperor Alexander, and the Duke's brother Constantine; his services were again rewarded with handsome fees and further titles. Dimsdale lived for nearly twenty years to enjoy his honours and emoluments, and dying at the ripe age of eighty-eight, was buried at Bishop's Stortford in the Quaker's burial-ground. Baron Dimsdale may not have been one of the greatest physicians, but he was certainly one of the best rewarded.

#### Cyto-Diagnosis in Nervous Diseases.

WITHIN the last few years attention has been drawn to the help that may accrue to diagnosis from the study of the cells contained in the fluids of the body. There is no doubt that, for instance, the cellular elements of a pleural effusion vary to a considerable extent with the

cause at work. This is, however, the simplest case that occurs, and we think that there has been, in some quarters, a tendency to expect equally speedy results from an examination of the fluids of other serous cavities. Some writers, for instance, have recorded rosy accounts of the great assistance given to the diagnosis of nervous diseases by the examination of the cells in the cerebro-spinal fluid. It has been held that an increase in the number of lymphocytes in that fluid is pathognomonic of meningeal irritation, and that it particularly occurs in the early stages of general paralysis of the insane and tabes dorsalis—the so-called parasyphilitic conditions. Fuller investigation, however, shows that these conclusions are somewhat hasty. Far from lymphocytosis of the cerebro-spinal fluid being confined to parasyphilitic cases, it has been found in such varying inflammations as herpes zoster, sciatica and parotitis, and in such intoxications as are due to tetanus, uræmia, and syphilis. At present one can hardly go further than the statement that while lymphocytosis is usually associated with tabes and general paresis, it is by no means to be relied on as diagnostic. It is, at best, but one point to be taken into consideration in basing a diagnosis on general grounds.

#### Frost-Bite in Tibet.

FROM a medical point of view perhaps the greatest hardship undergone by our troops in the Tibet Expedition was the exposure to great cold. Although in all campaigns soldiers are accustomed to suffer from both cold and exposure, yet a British army is rarely subjected to the Arctic cold encountered in the passage of the Himalayas. Lieutenant Davys, I.M.S., one of the medical officers attached to the expedition, has placed his observations on record, (a) and has given, in particular, an interesting study of frost-bite. Very rarely does cold, of itself, produce local necrosis, though this may occur if the cold is both severe and long continued. Much more commonly necrosis occurs as the result of carelessly applied heat. In Manitoba, where frost-bite is common, serious results rarely follow except in the case of new arrivals in the country, who, in their ignorance, immediately apply heat to the affected part. Similarly, among our troops in Tibet, the soldiers, entirely unused to the condition, as Dr. Davys notes, "used to hold the frost-bitten part practically in the fire." When this is done, a violent rapid œdema takes place, causing pressure on the already damaged tissue, followed by moist gangrene. As treatment, in mild cases rubbing is of itself effectual, but in more severe cases other steps must be taken to raise the temperature very gradually. The usual method is to immerse the part in a vessel of ice-cold water, whose temperature is then slowly raised by its being placed over a fire, friction being kept up throughout. In the most severe cases, where necrosis has

(a) *Indian Med. Gaz.*, July, 1904.

actually taken place, Dr. Davys found operative measures invariably necessary.

### A New Cancer Treatment.

DR. DOYEN, of Paris, informs us that he has not found the specific treatment for cancer any more than he has discovered the cancer microbe. He has discovered in the neoplastic tissues a micro-organism which he has named micrococcus neoformans, of which the cultures, weakened by certain processes and additions of quinine or of arsenic, form the basis of his anti-cancerous serum. At the French Surgical Congress, held last week, he gave the technical details of the manufacture of his antineoplastic liquids, and insisted upon the fact that the production of toxins obtained by the cultures of micrococcus neoformans was delicate, and so slow that two or three years elapsed before it was ready to be utilised therapeutically. Doyen brought forward statistics of 242 cases of cancer of all sorts treated by his method. The following are the results:—Forty-two apparently absolute cures, some of them now of four years standing. In 128 cases the treatment has given no result because it was commenced too late or interrupted too soon. Six patients died accidentally who were cured of their cancer, and the cases of twenty others have not been followed up. The following conditions are suitable for serum treatment, namely, all cases of malignant tumours which are doomed to relapse after operation; all confirmed cancers in which total removal cannot be practised; all tumours inoperable from the fact of their size or because important organs are involved. Dr. Doyen has kindly sent us a report of his address published in the *Bulletin Medical*, and from it we learn that he has considered the possibility of an anti-cancer vaccination giving immunity for a considerable period to susceptible persons.

### Chronic X-ray Dermatitis.

CERTAIN daily newspapers have raised the ghost of a well-known malady—as is their wont—and have done their best to make the blood of the public turn to water with their turnip-headed wonder. The fact that workers with the Röntgen rays are subject to an extremely chronic, distressing and incurable inflammation of the hands has at length penetrated the recesses of Fleet Street. The further fact that several cases of cancer have developed in connection with chronic X-ray injury seems to have inexpressibly inflamed the editorial imagination; the yellow press of the kingdom has been accordingly flooded with startling headlines, pictures, interviews and startling columns horrid with fact and fancy. Among the interviews we regret to see one with a Midland worker in the X-rays, who has apparently so far forgotten the unwritten rules of the medical profession as to furnish his experiences to a reporter, to be published under his own name. The views of a London specialist have been quoted copiously in

relation to a book, for which notice he is obviously not answerable. As a matter of fact the chronic dermatitis of Röntgen-ray workers has been known for a long time, and was described fully some six or seven years ago in the book which is the standard English authority on the Röntgen rays in medical work.

### Imperial Sanitary Commissioner for India.

THE scheme of sanitary administration for India that was recommended by the Plague Commission has been some years in meeting with recognition at the hands of the responsible Government, but with plague still rife in the country the staff of the medical department seems to have been too busy to attend to other duties than the immediate occasion required. The Government have at last determined to start putting the scheme into operation, and their first step has been the appointment of an Imperial Sanitary Commissioner for the whole Empire, whose duties will be entirely severed from those of the Director-General of the Medical Service. This is certainly a step in the right direction and the salary fixed for the new post, Rs. 2,000 to Rs. 2,500 a month, is, on the principle that people value a man's advice at what they pay him for it, an earnest that his recommendations will be regarded seriously. A somewhat refreshing feature, too, is the fact that a comparatively junior officer, Major Leslie, has been appointed to the position, which looks as though the Government wished to begin with an open mind, free from tradition and bias. The Sanitary Commissioner will advise the Local Government as to the principles on which their health organisation should be moulded, and how it should work, as he will have under his charge the very important department dealing with the institutes and laboratories for carrying on research-work and the manufacture of curative and minimising sera in India. To the Imperial Government he will act as sole adviser on all sanitary questions, and his recommendations will not have to pass through the office of the Director-General. It seems rather curious that the creation of an office which is practically that of a Minister of Public Health should be recognised as necessary and salutary in one of our dependencies, whilst in the Mother Country any proposal to create a similar post is hardly regarded seriously.

### PERSONAL.

DR. LIONEL H. WEATHERLY will preside at the annual dinner of the Bristol Medical School, to be held on October 28th, on which occasion Sir William Church will be the guest of the evening, and earlier in the day will distribute the prizes on behalf of the Faculty of Medicine of the University College, Bristol.

THE Sanatorium at Quarrier's Homes, Bridge-of-Weir, recently acquired by the Paisley Association for the Prevention of Consumption, was formally opened on the 15th inst., by Sir Thomas Glen-Coats, Bart., of Ferguslie Park, Paisley.

DR. ANDREW GRAHAM, of Currie, on the occasion of his semi-jubilee of practice in the district, was

entertained last week at a complimentary dinner in the Gibson Craig Memorial Hall, Currie.

THE new crematorium of the City of London Cemetery, Little Ilford, Essex, was opened by William Joseph Downes, Esq., Chairman of the Sanitary Committee, acting as the Burial Board of the City of London, Tuesday (yesterday).

IT is the intention of his friends in Belfast to entertain Professor Lorrain Smith at a public dinner before his departure from Queen's College to take up his duties at the Victoria University. The dinner will probably take place on November 3rd.

WE are officially informed that the Secretary of State for War has approved of the re-appointment for a further period of three years of the present civilian members of the Advisory Board for Army Medical Services:—Sir C. B. Ball, M.Ch., Dr. J. Galloway, Sir E. Cooper Perry, M.D., Sir F. Treves, Bart., K.C.V.O., C.B.

IT is announced that Sir Trevor Lawrence, the treasurer of St. Bartholomew's Hospital, and Mr. W. H. Cross, the clerk of the institution, have handed in their resignations, with intimation that they are willing to carry on the work until suitable successors have been found.

ON the 18th inst., Sir Frederick Treves opened a new hospital at Crewkerne, erected at a cost of £5,000.

DR. AMELIA WILKES LINES, who recently celebrated her eightieth birthday, is the oldest practising woman doctor in the world. She was the first woman to receive a diploma in the State of New York, and has practised in America since 1854.

DR. BYROM BRAMWELL will preside at the dinner of the Edinburgh University Club at the Criterion Restaurant, on Wednesday, November 9th, 1904. Tickets may be obtained from the Honorary Secretaries, James Taylor, 49 Welbeck Street, London, W., and G. A. Sutherland, 73 Wimpole Street, W.

MR. J. HALSEY MORTON has been appointed assistant secretary to the Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead, and Northwood, Middlesex.

THE Fitzpatrick Lectures before the Royal College of Physicians of London will be delivered by Dr. J. F. Payne, whose first lecture will deal with "English Medicine in the Anglo-Norman Period and Gilbertus Anglicus," while the second lecture will discuss "Ricardus Anglicus and the Teaching of Anatomy in the Middle Ages."

THE Bradshaw Lecture before the same College will be given by Dr. F. Foord Caiger on November 15th, on "The Treatment of Enteric Fever."

THE Horace Dobell Lecture of the London Physicians will be delivered by Dr. E. Klein, F.R.S., on November 22nd, the subject being "The Life-History of Saprophytic and Parasitic Bacteria and their Mutual Relation."

At the Royal College of Surgeons of England the Bradshaw Lecture will be given on December 1st by Mr. A.W. Mayo Robson, vice-president, on "Cancer and its Treatment"; and the Hunterian Oration by the president, Mr. John Tweedy, on February 14th, 1905.

At a meeting of the Aberdeen University Unionist Association on October 14th, the executive, after full consideration of the circumstances, again heartily and

unanimously approved of the prospective candidature of Sir Henry Craik, K.C.B., LL.D., and at the same time disavowed any connection with another Association recently formed under a similar title to their own.

LORD BALFOUR OF BURLEIGH, Chancellor of the University of St. Andrews, on Monday, October 17th, formally opened the new buildings which have been erected at a cost of £20,000 for the accommodation of the Medical School of University College, Dundee, which is now an integral part of that ancient University.

OF the total cost of the new St. Andrews buildings the University Court provided £14,000, and Sir William Gilvly Dalgleish gave a donation of £5,000.

THE annual dinner of the past and present students of the National Dental Hospital will be held at the Trocadero Restaurant on Saturday, November 19th, when the chair will be taken by Mr. Andrew Clark, D.Sc., F.R.C.S.

DR. WILLIAM COX, of Winchcombe, Gloucestershire, who has given his services to the parish church as honorary choirmaster and organist for thirty-two years, has recently been presented with a life-size portrait of himself, together with a tea service and salver in massive silver.

THE London companies of the Royal Army Medical Corps (Volunteers) will attend divine service at St. Bartholomew the Great on October 30th, when a sermon will be preached by the Rev. Sir Borradaile Savory, Bart., Rector of the church and Acting Chaplain of the companies.

WE are informed that the Awards Committee of the St. Louis Exhibition has conferred upon the Wellcome Chemical Research Laboratories a grand prize and three gold medals, in recognition of the importance and educational value of the chemical and pharmacognostical researches conducted under the direction of Dr. Frederick B. Power.

LIEUTENANT-COLONEL WILLIAMSON, R.A.M.C., at present on the Aldershot Medical Staff, has been appointed Administrative Medical Officer in India.

THE Paris *Matin* announces the death of Dr. Tillaux, Professor of Surgery, President of the Academy of Medicine, and Grand Officer of the Legion of Honour.

DR. ARTHUR NEWSOME (Medical Officer of Health for Brighton) last week delivered an address at the inaugural meeting of the York Medical Society, selecting as his subject "Social Evolution and Public Health."

## Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

### SCOTLAND.

#### NEW MEDICAL SCHOOL AT DUNDEE.

LORD BALFOUR OF BURLEIGH, Chancellor of the University of St. Andrews, opened the new buildings at University College, Dundee, on the 17th inst. Hitherto the development of medical teaching at Dundee has been greatly hampered by the inadequacy of the premises in which it has been carried on, but the new accommodation provided will, it is hoped, meet all demands for many years to come. Little attention has been paid to architectural adornment, the main object having been to secure internal efficiency and convenience. The lecture-rooms have accommodation for a total of 500 students, and there is a specially fine dissecting-room equipped with all the most modern appliances for the teaching of anatomy. Lord Balfour, in performing the opening ceremony, said that the day marked the completion of the first step which was in view—namely, the establishment of a great medical

school in Dundee—when the union between St. Andrews University and University College, Dundee, was first proposed. Though unforeseen difficulties had arisen, the union was finally accomplished in 1897, at which date Dundee had chairs which provided for the education of students during the first two years of their course. After the union new chairs were added, and now a complete medical curriculum could be gone through in Dundee. The new premises had cost only a little in excess of the estimated £20,000; they would accommodate classes for anatomy, physiology, pathology, materia medica, surgery, obstetrics, medical jurisprudence, &c., with museums, laboratories and classrooms for various subordinate subjects. While congratulating all those concerned on the rapid progress which had been made during the two years which had passed since Mr. Carnegie laid the foundation-stone, Lord Balfour said that they must not yet think they were in such a position that they could afford to "rest and be thankful." Other important developments were to be inaugurated, even during the present session. Property had been acquired which was about to be converted into a University library and a students' union. A munificent benefactor, Mr. Fleming, of London, had given a large sum for a gymnasium and fives court. The speaker concluded by hoping that the new medical school would fulfil all the bright future foretold for it. Speeches were also made by Principal Donaldson, the Earl of Camperdown, and Principal Yule Mackay, and the proceedings terminated by a luncheon at which about one hundred gentlemen were present.

**ST. ANDREWS UNIVERSITY RECTORSHIP.**—At a recent meeting of the students there was a practically unanimous opinion expressed in favour of electing Mr. Andrew Carnegie for a second term of office as Lord Rector. The name of Mr. Andrew Lang was also proposed; he has many warm friends among the students, but the measure of support given him at the meeting was not such as, meantime at least, would warrant his nomination.

**PROPOSED AGE LIMIT AT THE ROYAL INFIRMARY, EDINBURGH.**—It is understood that the Joint Committee of the managers and contributors to the Royal Infirmary appointed in the early part of the year to consider the question have drawn up a report recommending that it be left entirely to the managers to grant or refuse applications from members of the staff for an extension of five years in their appointments. The original proposal was that the physicians and surgeons should retire at sixty-five, and objection was then taken to the exclusion of the University professors from the operation of the rule. Apparently the Committee have simply reported in favour of the *status quo*—a minority of two favoured the adoption of the age limit.

**OPENING OF THE SESSION AT EDINBURGH UNIVERSITY.**—The medical classes were opened for the winter on the 18th, for the most part without any formal introductory lectures, the professors at once beginning the year's work. Professor Chiene, however, commenced his lectures on surgery by an address on the responsibility of surgeons, and Professor Simpson devoted the first lecture of the course on obstetrics to a historical sketch of the teaching of midwifery in the eighteenth century, in which he showed that the Edinburgh chair was the oldest in Europe, its date anticipating that of the Florentine Chair of Midwifery (1728) by two years.

**QUEEN ALEXANDRA SANATORIUM AT DAVOS.**—Lord Balfour addressed a meeting in Edinburgh in favour of this object on October 18th, the outcome being, in addition to the intimation of several substantial donations, the formation of a Committee to secure help for the scheme in the Edinburgh district. Since the Glasgow meeting was held about a week ago the Lord Provost of Glasgow has received nearly £200 for the same object.

A SUM of nearly £15,000 has now been received on behalf of the present year's collection for the Hospital Saturday Fund, the result mainly of weekly or other periodical contributions in the workshops, &c., of London.

## Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

### THE TREATMENT OF INOPERABLE CANCER.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—While thanking you for your kind reference to myself in the editorial columns, respecting my paper, "On the Treatment of Inoperable Cancer by Hypodermic Medication," published in your last issue, I would like to make it plain that I do not claim to be the originator of this method of treatment, but only to draw attention to the use of chian turpentine, and to the use of the soap solution of Mr. J. H. Webb, of Melbourne, in this connection.

I am, Sir, yours truly,

JOHN A. SHAW-MACKENZIE.

42 Green Street, Park Lane, W.,  
October 20th, 1904.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—In your "Notes on Current Topics" of last week, you say that "Dr. Shaw-Mackenzie has made the pioneer move in the necessary experimentation," *i.e.*, in cancer. Though I consider this an exceedingly small matter, as experiments with hypodermic injections in the treatment of cancer are neither original to Dr. Mackenzie nor to myself, yet for the sake of accuracy I would like to say that I suggested to Dr. Mackenzie that he should try hypodermic injections in cancer, and told him what I was then using in that way.

I am, Sir, yours truly,

GEORGE E. KEITH.

7 Manchester Square, W., Oct. 21st, 1904.

[The modification of the above-quoted statement had already reached us from Dr. Shaw-Mackenzie himself. Our reference was rather to the particular *technique* than to the principle.—ED.]

### A DISCLAIMER.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—I have seen an article in your paper, entitled "Eye Massage," in which occurs the following sentence:—"Under the leadership of Mr. Stephen Coleridge, they (the anti-vivisectionists) have practically declared war to the knife with the medical profession."

I desire to say that I have never in my life attacked the medical profession, and I shall therefore feel obliged if you will be so good as to produce any utterance of mine that you think affords you any justification for this statement of yours.

I have been told that there are some thirty or forty thousand members of the medical profession, and I know there are but 350 licensed vivisectionists in this country, and not even all of these hold medical degrees.

You might with as much justice accuse a man of attacking the art and profession of music because he objects to hurdy-gurdies.

As to Mr. Stephen Smith and eye massage, as the National Anti-Vivisection Society which I represent and I myself individually have never had any connection of any kind with the Anti-Vivisection Hospital, I fail to see why my name should be introduced into your article on the subject.

I am, Sir, yours truly,

STEPHEN COLERIDGE.

92 Victoria Street, London, S.W.,  
Oct. 18th, 1904.

[We insert the above letter with pleasure, as we should be sorry to treat an opponent in any way open to a suspicion of unfairness. We do not, of course, hold the Hon. Stephen Coleridge responsible for all the acts of anti-vivisectionists generally, nor did we state that he or the National Anti-vivisection Society were particularly concerned in the establishment of the Anti-vivisection Hospital. He will, however, excuse us for designating him as leader

of the anti-division movement, although many anti-divisionists do not follow his banner, for since Miss Cobbe's retirement he has, by his energy and championship, come to be regarded as the protagonist of the cause. As Mr. Coleridge has lost few opportunities of attacking hospitals with medical schools attached to them—institutions which are representative of all that is best in the thought and feeling of the medical profession—besides many medical men from Lord Lister downwards, he can hardly complain that he is misrepresented when we say he "practically" wages war against the medical profession. A man who continually attacks hurdy-gurdies may, not improperly, be said to be waging war with the organ-grinding profession. The principle of trying to divert public subscriptions from hospitals in which any member of the staff has ever performed an experiment on a lower animal is one against which we protest, and as late as September 20th of this year Mr. Stephen Coleridge attempted to influence such a diversion of funds by letters to the *Daily News* and *Morning Leader*. The gross statistical fallacy by which Mr. Coleridge arrived at the results he put forward in that letter were exposed by Mr. Downton at the time.—ED.]

#### THE MIDWIVES ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Midwives Act, as you are aware, has very seriously altered the position of the medical man with regard to the practice of midwifery, the greater part of which will probably in the future be done by registered midwives. The Act compels the midwife, under certain scheduled conditions, to demand the assistance of a medical man, and to state in writing the nature of the necessity. The Act does not, however, make any arrangement for the payment of the doctor's fees, nor is it compulsory on the doctor to obey the midwife's summons.

The Medical Guild has fully considered the question, and at the last quarterly meeting the following resolution was adopted:—"That when medical practitioners choose to attend confinements at the request of midwives the minimum fee charged should be a guinea, to be paid at the time when possible. This should be carried out for the present as a tentative arrangement till fresh legislation, dealing with medical fees, has been brought forward."

The whole question is, of course, in a transitory stage, and it is important not to do anything against the interests of the profession by ill-considered individual action, especially by cutting down the minimum fee.

We are, Sir, yours truly,

D. OWEN,

J. H. TAYLOR,

Hon. Secs. of The Medical Guild.

Manchester, October, 1904.

[We entirely approve of the attitude adopted by the Medical Guild with regard to this important matter, and desire to urge strongly on medical men the necessity for united action. If a firm stand is made now, the public will be compelled to recognise the rights of the medical profession. Otherwise, an attempt will be made to establish a custom of medical attendance in these cases at a ridiculous fee.—ED.]

#### PROPOSED STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of October 19th, you refer to the above grave question under the somewhat sensational heading, "A Short Way With Lunatics." Now such a heading is hardly in keeping with that fair style we are—thank Heaven!—accustomed to meet with in THE MEDICAL PRESS AND CIRCULAR. If I adopt your description—"A Short Way With Lunatics"—it would, to me at least, mean that lunatics are to be killed. Had you said, "A Short Way With Lunacy," no one could honestly object.

I am more than pleased to see that Dr. F. J. Smith—

recognising that lunacy and other forms of degeneracy are so greatly on the increase and that there is no real cure—has followed me in adopting my suggestion of sterilisation of special degenerates. I would, however, differ just a little from him. He advises that a woman with puerperal mania who has murdered her child should undergo oöphorectomy. I would not wait in such case for the murder of her child. If she developed insanity during pregnancy, the puerperium, or suckling, I would advise that she be forthwith sterilised, and I question if it would not be a good thing for our race if abortion were brought on if she developed insanity a few months after conception. Dr. Smith's plan of waiting until the child is murdered is, perhaps, good, in so far as it would prevent the poor degenerate child from living under a mental curse handed down from its parent, or even becoming ultimately a mother. I would, however, suggest that the child be sterilised. Please note, I do not for an instant suggest that Dr. Smith advocates the killing of the child by its insane mother. I have come in contact with so much cackling and garrulous accusations of having advocated suicide by the insane, when I published my book upon the above proposal, that I am now willing to labour a point with words, so that the meanest intellects—if honest—can understand.

I am, Sir, yours truly,

ROBERT R. RENTOUL.

Liverpool, October 22nd, 1904.

#### ALCOHOL AND INSANITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a temperance reformer, let me first thank you for the attention and able treatment which the question of the abuse of alcohol constantly receives in your paper. The lecture by Dr. Clouston, published in THE MEDICAL PRESS AND CIRCULAR of October 12th, furnishes most powerful arguments to the cause of temperance, and the value of these arguments would not be much discounted if the suggestion made by Dr. Walsh to-day (October 19th) were to turn out correct. Whether in some instances incipient insanity develops dipsomania, or in other cases alcoholism produces insanity, it is equally evident that much good would be done if drinking could be diminished, or, at least, if no alcoholic drink should be procurable save such as is of the purest and least toxic manufacture. The harm done by beer is infinitesimal compared to that brought about by the raw spirits which the majority of drunkards—the poorer classes—consume. It is spirit-drinking which carries most to ruin, and the ruin is more quickly and certainly brought about owing to the fact that the spirit is crude, unrefined, and loaded with fusel oil and other kinds of impurity. I am not a believer in the power of laws to do away with drunkenness, but I think the Legislature might well attempt to prevent the sale of all alcoholic drinks which by their preventable impurity act as powerful poisons upon the pitiable victims of drink craving.

I am, Sir, yours truly,

A TEMPERANCE REFORMER.

October 19th, 1904.

#### PUBLIC SCHOOLS AND FLOGGING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Why is it that, in almost every controversy on the flogging question, some public school man comes forward to assure the public that he, even he, was himself flogged in his boyhood? Does he do so from a philanthropic desire to supply an element of comedy to a somewhat dry discussion? Or does he imagine that his own early birchings are, in some mysterious way, really relevant to the point at issue? Thus, in the recent inquiry into the birching scandal at the Sparkhill Police Court, Birmingham, the Chairman, Mr. R. H. Amphlett, K.C., is reported to have observed that "he knew the birch very well when he was at Eton." I can quite believe it; but what possible bearing has it on an inquiry into the conduct of a superintendent of police who birched a boy illegally? Can it be that these gentlemen who obtrude their

private experiences in a public discussion intend us to understand that, in view of the superlative excellence to which they have now attained, any punishment which they underwent in youth must of necessity be good for other people, whether in itself legal or illegal? If that be their meaning, the reasoning does not seem very cogent; indeed, their lack of logic raises sad suspicions that they were birched in vain. We prefer to think that they merely wish to enliven the proceedings by a jocose, though irrelevant remark. Perhaps Mr. Amphlett will enlighten us?

I am, Sir, yours truly,

PUZZLED.

October, 1904.

[The use of the birch generally is a subject on which the views of the medical profession could hardly fail to be most interesting and valuable.—ED.]

#### "PUBLIC OPINION" AND THE HOSPITAL PENNY FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Owing to the fact that the above fund has been severely attacked by the *Hospital* and various other newspapers, we should be glad if you will make the following fact known through the medium of your journal. The principal of these attacks has been that 25 per cent. of the total received for the hospital stamps goes into the promoter's pockets. This is not the case; the whole of the prizes and expenses in the administration of the fund is paid out of the 25 per cent. in question, and this absorbs that amount, which has been arrived at after very careful consideration.

Mr. George Herring, who has been concerned in almost every class of scheme for obtaining money for the hospitals, writes us as follows:—

DEAR SIR,—I think your opponents have treated the scheme unfairly. If they objected on the score of its being immoral to give prizes in the cause of charity, it is a point which each person must judge for himself; but if on the score of the deduction of 25 per cent., I confess candidly that at bazaars and other society methods of collecting money for charities, upwards of 50 per cent. is frequently deducted for expenses. I fail to see the objection to your deducting the 25 per cent. Then, as I understand, you propose to deposit or properly guarantee the £5,000 prizes, therefore the hospitals must benefit to the extent of £15,000 before you are recouped. It is, therefore, you that run the risk, and in my mind a great risk, as you are opening up fresh ground which can only be worked by an army of energetic workers, who expect money prizes, and do not work for charity only, but for themselves. Hence, I see no objection to the 25 per cent. Having written you my views I yet counsel you not to force the scheme, if the hospitals are not in favour of it, as I think the public will not take your side against the general verdict.—Yours truly,

(Signed) GEORGE HERRING.

1 Hamilton Place, Piccadilly, W.

October 13th, 1904.

Upon this letter we had lengthy interviews with Mr. Herring, who is thoroughly interested in the scheme, and considers it should be accepted in a universal way. Mr. Herring is further strictly in accord with our views on the suggestion made by the *Hospital* in the last week's issue of that journal, in calling a meeting of the leading authorities of the whole of the London hospitals. We are taking an early opportunity of doing this, and the meeting will be announced in the course of a few days.

Other important announcements will be made at this meeting, which we hope will satisfy both the hospitals and the Press as to the genuine work of the fund.

I am, Sir, yours truly,  
THE HOSPITAL PENNY FUND,  
M. H. GOLDMAN, Secretary.

13 Henrietta Street, and 31 Maiden Lane, W.C.  
October 19th, 1904.

[The principal objections, so far as we know, that have been made to this scheme advocated by *Public Opinion*, is that (a) a large percentage of receipts fail to reach the hospitals; (b) a big advertisement is secured for the journal concerned; (c) the Committee is not sufficiently representative either of the medical charities or of the public; (d) the prize system is bad. Without here going into the merits of the case it may be stated broadly that (c) and (d) seem to us the most pertinent points for inquiry.—ED.]

#### Obituary.

ROGER PORTINGTON GOODWORTH, J.P.  
M.R.C.S., L.S.A.

WE regret to announce the death on October 7th of Dr. Roger Portington Goodworth, of Winterton, near Doncaster. Born in 1846, Dr. Goodworth was a son of William Henry Goodworth, a surgeon in the West Riding of Yorkshire. Later he entered the medical school of the London Hospital, whence he took the qualification of M.R.C.S.Eng., L.S.A.Lond., and L.R.C.P.Edin. in 1876, and not long afterwards went into partnership with the late Mr. Sadler of Winterton. Dr. Goodworth was appointed a Justice of the Peace for the County of Lincoln, and also served for some years upon the County Council. In politics he was a Conservative, while he was a strong supporter of the Established Church. A man of wide sympathies, he has left a large circle of friends and patients to lament his loss. He is succeeded by Frederick Henry Hand, M.D., M.R.C.S.

DR. FREDERICK HENRY HUME.

DR. FREDERICK HENRY HUME, of Islington, who died early last month, devoted the greater part of his professional career to work in that neighbourhood. A student of St. Thomas's Hospital Medical School, he became M.R.C.S.Eng. and L.S.A. in 1864, and graduated M.D. some twenty years later at St. Andrews. He was a man of great energies, and held a large number of appointments, which he conscientiously attended to until a few years ago, when he became crippled with gout.

DR. JAS. B. RUSSELL, OF EDINBURGH.

THE death has occurred, at Edinburgh, of Dr. James Burn Russell, in his sixty-seventh year. He graduated at the University of Glasgow in 1858, and was elected a Fellow of the Glasgow Faculty of Physicians in 1869. For many years he held the office of Public Officer of Health at Glasgow, and was the first to bring into prominence in that city the question of the housing of the poor. Six years ago he left Glasgow for Edinburgh, when he was appointed medical member of the Local Government Board for Scotland.

#### Medical News.

Royal College of Physicians of Ireland.

At the stated annual meeting of the Royal College of Physicians of Ireland, held on St. Luke's Day, the following officers were elected for the coming year:—

President.—W. J. Smyly, M.D.

Vice-President.—E. E. Lennon.

Censors.—E. E. Lennon, Alfred R. Parsons, M.D., J. H. R. Glenn, M.D., W. R. Dawson, M.D.

Additional examiners to take the place of an absent censor or examiner.—Medicine: W. J. Thompson, M.D.; Midwifery: W. C. Nevill, M.D.; Medical Jurisprudence and Hygiene: A. Nixon Montgomery.

Examiner for the Licence to Practise Midwifery.—A. J. Horne, Henry Jellett, M.D.

Examiners for the Membership.—Clinical: J. Magee Finny, M.D., E. E. Lennon; Practice of Medicine: Walter G. Smith, M.D., Alfred R. Parsons, M.D.; Pathology: H. C. Earl, M.D., A. C. O'Sullivan, M.D.

Additional Examiners under the Conjoint Examination Scheme.—Biology: E. MacDowel Cosgrave, M.D.;

Chemistry: Professor Lapper, N. M. Falkiner, M.D.; Physics: George J. Peacocke, M.D.; W. A. Winter, M.D.; Pharmacy, *Materia Medica*, and Therapeutics: H. C. Drury, M.D., Martin Dempsey, M.D.; Physiology, H. C. Earl, M.D.; Pathology: A. C. O'Sullivan, M.D.; Medicine: J. Murphy, R. Travers Smith, M.D.; Hygiene and Forensic Medicine: Henry T. Bewley, M.D.

*Examiners for the Conjoint Diploma in Public Health.*—Meteorology, Sir John Moore, M.D.; Hygiene: Henry T. Bewley, M.D.; Chemistry: Professor Lapper.

*Extern Examiners in Preliminary Education.*—Professor W. E. Thrift, F.T.C.D., Mr. William Kennedy F.T.C.D.

*Representative on the General Medical Council.*—Sir John Moore, M.D.

*Representatives on the Committee of Management.*—J. M. Finny, M.D., Walter G. Smith, M.D., James Craig, M.D.

*Treasurer*, H. T. Bewley, M.D.; *Registrar*, James Craig, M.D.; *Librarian*, R. G. J. Phelps; *Architect*, A. E. Murray, C.E.; *Law Agents*, Messrs. Stephen Gordon and Son; *Agent to the Trust Estate*, C. U. Townshend, J.P.

Dr. J. A. Matson, Dr. T. P. C. Kirkpatrick, and Dr. F. C. Purser were elected Fellows of the College.

In the evening the annual banquet of the President and Fellows took place in the College Hall.

#### The New President of Queen's College, Cork.

As we go to press, it is officially announced that Dr. Bertram Coghill Windle has been appointed to the Presidency of the Queen's College, Cork, in succession to Sir Rowland Blennerhassett, Bart., who has resigned. Professor Windle is a distinguished Irishman. He was educated at Trinity College, Dublin, and subsequently held different anatomical posts in Ireland and England, until finally he was elected Professor of Anatomy in the University of Birmingham. He is also a member of the General Medical Council.

#### Royal College of Surgeons of England.

NOTICE will be found in another column of the annual meeting of Fellows and Members of the College, which will be held on Thursday, November 17th, at 3 p.m. when a report from the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the Secretary, and can, if they so desire, register their names as wishing to receive the Report annually. A printed copy of the agenda will be issued to any Fellow or Member who may apply for one on or after November 14th.

#### French Asylum Scandal.

A SENSATIONAL case will shortly come before the Paris Courts in which revelations are expected regarding the conduct of lunatic asylums. An action is being brought by M<sup>me</sup>. Pierron against her husband for illegal detention in an asylum. The Pierron couple were always quarrelling, and it was alleged that M. Pierron got a lunacy certificate signed by Dr. Laurens, and then informed the police, who, in face of the certificate, ordered the lady to an asylum. After three days, however, the medical officer of the asylum, Dr. Garnier, examined her, and pronounced her to be sane. She was accordingly released, but meanwhile the husband had sold up the home and disappeared. After a long illness, brought on by her sufferings, M<sup>me</sup>. Pierron commenced an action, Dr. Laurens being sued also for complicity.

#### Largest Hospital in the World.

THE new infirmary in Berlin promises to be the largest hospital in the world. When finished next year it will contain 2,000 beds. In connection with the hospital which will be known as Rudolph Virchow's Krankenhaus, there will be a pathological and anatomical institute, a medico-mechanical institute, a magnificently-appointed pharmacy, and a separate house for Röntgen-ray appliances. The entire staff of physicians, nurses and servants will number 650. There will also be a school for training nurses. The largest hospital at present in Germany is near Hamburg, with 1,630 beds. The new hospital will not only be the largest in the world, but its builders boast

that from hygienic and sanitary points of view it will surpass all others, both in Europe and America.—*Chronicle.*

#### Awards at the St. Louis Exhibition.

GRATIFYING evidence of the recognition extended to British commercial enterprise is furnished by the honours awarded by the Committee of the St. Louis Exhibition to Messrs. Burroughs Wellcome and Co.'s exhibit of "Wellcome" Brand Chemicals, "Tabloid" and other pharmaceutical products, and "Tabloid" and medical equipments. Three grand prizes and three gold medals have been conferred for the scientific excellence of these products. The same firm has also been awarded for its Wellcome Chemical Research Laboratories the distinction of a grand prize and three gold medals, in recognition of the importance and educational value of the chemical and pharmacognosical researches conducted in these laboratories under the direction of Dr. Frederick B. Power. Also one grand prize and one gold medal for the Wellcome Physiological Research Laboratories for bacteriological research and preparations, and for educational work. The Grand Prix has been awarded to the Apollinaris Company, Limited, for the Apollinaris natural mineral water.

Mr. Wm. Martindale, manufacturing chemist, of London, has been awarded a Silver Medal for his exhibit of fine chemicals, pharmaceutical products and emergency preparations, Galenical and surgical.

#### The Royal Waterloo Hospital for Children and Women.

THE Royal Waterloo Hospital for Children and Women is being rebuilt and enlarged, and is now rapidly approaching completion. The following have recently announced their gracious intention of becoming patrons of this Institution:—T.R.H. the Duke and Duchess of Connaught, H.R.H. Princess Henry of Battenberg, H.R.H. Princess Frederica Baroness von Pawel Rammingen, T.S.H. Prince and Princess Alexander of Teck, H.R.H. the Grand Duke of Hesse, H.R.H. Prince Charles of Denmark, H.R.H. Princess Charles of Denmark, H.R.H. the Crown Princess of Greece. The above list is in addition to T.M. the King and Queen, T.R.H. the Prince and Princess of Wales, H.R. and I.H. the Duchess of Saxe-Coburg and Gotha, H.R.H. the Princess Christian of Schleswig-Holstein, H.R.H. The Duchess of Albany, and H.M. the Queen of the Hellenes, who for many years have most graciously given their patronage and support.

#### Jervis Street Hospital, Dublin.

At a meeting of the Governors of this Hospital, on October 17th, Mr. Mathew Burke Savage was unanimously elected physician to the hospital in the room of Dr. W. J. Martin, who has resigned, and Mr. J. F. L. Keegan, surgeon to the hospital, in the room of the late Dr. J. J. Cranny.

#### King Edward's Coronation National Fund for Nurses.

A MEETING of the Council of the above society was held on the 12th inst. The Right Hon. the Earl of Meath, President of the Council of Management, presided. The hon. treasurer's accounts for the quarter ending October 11th were read and passed, and applications for membership from nurses were considered and confirmed. The hon. secretaries drew the attention of the council to the fact that the subscription of the nurses as members and the interest of the money invested was not sufficient to allow the society to render help as freely as it would wish to those nurse members who are incapacitated through ill-health. The council appointed a sub-committee, consisting of Sir Andrew Reed, K.C.B., Sir William Thomson, C.B., F.R.C.S., Mr. Andrew Beattie, D.L. and hon. secretaries with power to add to their number, to consider the matter.

WE regret to learn that Dr. Hewetson, of Reigate, was seriously injured in a motor-car collision on Monday. Both he and his servant were thrown violently to the ground, and on examination by Dr. Ross to whose house he was taken, it was found that he had received such injuries internally that it was impossible to remove him. The servant was also cut about the legs, and the car was smashed.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

### THE VERNON HARCOURT INHALER.

A correspondent has drawn our attention to a recent death under chloroform at University College Hospital. He writes as follows:—"What about the Vernon Harcourt Inhaler? The Hospital where this case actually occurred, being the home of that apparatus, it would be interesting to learn has it been used in that case? If not, why not?" The newspaper cutting enclosed by our correspondent did not state how the chloroform was administered. It would be interesting to ascertain the point, which no doubt would be readily done by the hospital authorities. The question of safety in anaesthetics is one of supreme importance and the inventor of the appliance in question is far too scientific a man, to treat adverse facts—if present—in anything but a spirit of absolute candour.

**STRATHCONA'S HORSE.**—A correspondent, R.A.M.C., asks if any special prevalence of alopecia areata has been noted in connection with the late South African War. In reply it may be stated that a dermatologist whom we have consulted has met with a large number of cases. The wearing of close fitting uniform caps, sometimes for weeks together, and the difficulties in the way of personal cleanliness would, to a great extent, account for the existence of the malady in unusual amount. Enteric fever would be another predisposing factor.

**L.S.A. (Bournemouth).**—The enterprising Bournemouth firm that offered twenty per cent. commission to all clergymen upon sales of "Dr. Auzona's Remedy for Gout," may now learn the composition of that vaunted specific. An analysis of the nostrum, recently published in the *Pharmaceutical Journal* shows it to consist mainly of syrup of buckthorn and citric acid. In a medical journal further comment is unnecessary. A prosecution for fraudulent pretences in representing a compound of that kind as curative of gout might conceivably be sustained in a court of justice.

**ANTI-QUACK (Wandsworth).**—We understand that in New York, the public is becoming alarmed by the enormous extent of the spurious drug business. Chemists complain that the revelations have led to a general decline in their legitimate business. Amongst the incriminating papers seized is a circular for druggists' use, containing a list of thirty-seven drugs and illegal articles put up to imitate genuine and vastly more expensive goods. It is only a matter of time for any thinking and self-respecting country to realise and exterminate this cruel industry. Great Britain is now the dumping ground of American quacks.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, OCTOBER 26th.

**HUNTERIAN SOCIETY** (London Institution, Finsbury Circus, E.C.).—8 p.m. Exhibition of Cases. 8.30 p.m. Clinical Evening.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.). 4 p.m. Mr. M. Ollier; Clinique. (Surgical.) 5.15 p.m. Sir A. D. Fripp: Recent Variations in the Technique of Certain Common Operations.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (North-Eastern Fever Hospital St. Ann's Road, N.).—2.30 p.m. Dr. H. Cuff: Demonstration on Fevers.

THURSDAY, OCTOBER 27th.

**BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY** (20 Hanover Square, W.).—8.30 p.m. General Meeting. 9 p.m. Presidential Address:—Dr. W. B. Davies: The Spa Treatment of Arthritis Deformans.

**NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Clinical Meeting. Exhibition of Clinical Cases.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. W. Ewart: The Preventive Treatment and the Protective Treatment of Chronic Heart Disease.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. J. E. Squire: The Arrest of Pulmonary Tuberculosis (demonstration of cases). (Post-Graduate Course.)

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture.—Dr. A. Giles: Diagnosis of Pelvic Tumours.

FRIDAY, OCTOBER 28th.

**CLINICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by discussion. Patients will be in attendance from 8 to 9 p.m.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.—4 p.m. Mr. N. Maclehoze: Clinique. (Eye.)

## Vacancies.

**Bury Infirmary.**—Junior House Surgeon. Salary £200 per annum, with board, residence and attendance. Applications to the Hon. Secretary, Dispensary, Knowley Street, Bury, Lancashire.

**Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.** Senior House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to Robert J. Bland, Secretary.

**Down District Lunatic Asylum, Downpatrick.**—Jun. Male Assis. Med. Officer. Salary £100 per annum, with furnished apartments, &c. Applications to the Resident Medical Superintendent.

**The Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Norwood, Middlesex.**—Senior Resident Medical Officer. Salary £100 per annum. Applications to William Morton, Secretary, 7 Fitzroy Square, W.

**London County Council Asylum, Horton, Epsom.**—Fourth Assistant Medical Officer. Salary £180 per annum, with board, furnished apartments and washing. Applications to E. W. Partridge, Asylum's Committee Office, 6 Waterloo Place, S.W.

**City of London Asylum, near Dartford, Kent.**—Medical Superintendent. Salary £200 per annum, with unfurnished house, coal, light, laundry and garden produce. Applications to Charles Fitch, Clerk to the Visiting Committee, Guildhall, E.C.

**Parish of St. Marylebone Infirmary, Rocham Street, Ladbrook Grove Road, Notting Hill, W.**—Male Assistant Medical Officer. Salary £110 per annum, with furnished apartments, ration, and washing. Applications to Henry T. Dudman, Clerk to the Board, Guardians' Offices, Northumberland Street, Marylebone Road, W.

**Warneford Hospital, Leamington.**—House Surgeon. Salary £100 per annum, with board, washing, and apartments. Applications to G. T. Poole, Secretary.

**Nottingham Children's Hospital.**—House Surgeon. Salary £100 per annum, with board and residence. Applications to A. F. Kirby, Secretary, Albion Chambers, King Street, Nottingham.

## Appointments.

**CLARKE, W. ST., M.D.** Toronto, Clinical Assistant to the Chelsea Hospital for Women.

**COLBRIDGE, A., M.R.C.S., L.R.C.P.Lond.**, Clinical Assistant to the Chelsea Hospital for Women.

**CUMMINGS, WILLIAM, M.B., B.Ch., B.U.I.**, Physician to the Cleveland Hydropathic Institution, Somerset.

**GIDDINGS, G. T., M.D.** Durh., Public Vaccinator of Beckenham.

**LITTLE, E. M., F.R.C.S. Eng.**, Honorary Assistant Medical Officer to the Southport Infirmary.

**LLOYD, W. GIBBS, M.Sc., M.B., Ch.B.** Vict., Medical Officer and Public Vaccinator to the Walton Workhouse Infirmary, Liverpool.

**NUTTALL, J. S. W., M.B., Ch.B.** Vict., Assistant Medical Officer to the Walton Workhouse Infirmary, Liverpool.

**SMITH, E. CASSIUS, M.B., Ch.B.** Glasg., House Surgeon to the Victoria Hospital for Children, Chelsea.

## Births.

**COPLEY.**—On October 14th, at Palace Street, Drogheda, the wife of Dr. S. Copley, of a daughter.

**JAMES.**—On October 18th, at Hungerford, Berks, the wife of Robert Blake James, M.R.C.S. Eng., L.R.C.P.Lond., of a son.

**LING.**—On October 20th, at 12 Harley House, London, the wife of Maurice E. Ling, M.D., of a son.

**SWALES.**—On October 18th, at Oak Villa, West Kirby, Cheshire, the wife of Edward Swales, M.R.C.S., L.R.C.P.Lond., of a son.

## Marriages.

**COFFEY—FITZGERALD.**—On October 18th, at Mitchelstown, by the Rev. P. Casey, of St. Colman's College, Fermoy, assisted by the Rev. William Casey, P.P., abbeycale (both cousins of the bride), the Very Rev. Canon Rice, P.P., Mitchelstown, Rev. T. O'Donoghue, Rev. Father Flannery, and the Rev. O. W. Ellard, Dr. Edward R. Coffey, 14 Westbourne Place, Queenstown, and late of Farnham, Surrey, to Nellie Teresa, only daughter of Mr. Patrick Fitzgerald, Mitchelstown.

**FOSTER—WATSON.**—On October 22nd, at St. Peter's, Bayswater, William, second son of the late Birkett Foster, member of the Royal Society of Painters in Water-colours, to Mary, daughter of the late William Watson, M.R.C.S., of Lancaster.

## Deaths.

**BISHOP.**—On October 22nd, at The Platts, Watford, Georgina Elreia, widow of the late Thomas Bishop, Esq., of Bramcote, Notts, and daughter of the late John Pidcock, Esq., M.D., of Watford, in her 98th year.

**KELSON.**—On October 18th, at his residence, Beckington, Guernsey, Frederic Hughes Kelson, M.R.C.S.L., formerly of Ceylon, in his 86th year.

**MOORE.**—On Sunday, October 23rd, at his residence, 29 Upper Merrion Street, Dublin, Robert Henry Moore, F.R.C.S.I., in his 89th year. Funeral private. No flowers, by request.

**SLACK.**—On October 24th, at Derwent Hill, Keswick, Anne Aintworth Slack, widow of the late Robert Slack, M.D. aged 71.

## Paris Clinical Lectures.

### TAPPING OF THE LUMBAR REGION.

By DR. G. MILIAU,

Chef de Clinique de la Faculté à l'Hôpital St. Louis.

[SPECIALLY REPORTED BY OUR FRENCH CORRESPONDENT.]

UNDER the name of lumbar puncture is designed a little operation, consisting in piercing the dural cul-de-sac by a trocar and giving issue to the cephalo-rhachidian liquid.

This operation was practised for the first time by Quincke, of Heel, in 1890. This author inserted his trocar into the third or fourth lumbar space in the middle line in children, and half an inch to the right of this line in adults. It was Chipault who recommended the puncture to be made between the fifth lumbar vertebra and the sacrum, for the reason that this space is larger than those between the lumbar vertebrae, and that it corresponds to the most dilated portion of the subarachnoid cul-de-sac. In this space also there is less risk of wounding the caudal nerves. Tuffier, however, who was a great partisan of anæsthesia by cocaine injected into the medulla, preferred the fourth lumbar space as more easy to find, it being situated exactly on the line drawn between the two iliac crests.

*Operation.*—To puncture the lumbar space a long and strong platinum needle is used. The pointed extremity is bevelled, while the other is formed so as to adapt itself to a Pravaz syringe. The patient being seated, the body bent forwards, and the arms well in front, after having traced with great care the line joining the two iliac crests and disinfected the region so as to render it completely aseptic, the operator introduces the needle on this line to the right of the vertebral column, and about half an inch of a vertical line drawn between the spinous apophyses. The needle is directed forwards and a little inwards; it passes through successively the skin, subcutaneous cellular tissue, lumbar aponeurosis and the sacro-lumbar muscles. It passes between the two vertebrae, perforates the yellow ligament, and after piercing the membranes it penetrates in the cul-de-sac. Immediately drops of a more or less limpid liquid issue from the free extremity of the needle. Such is in all simplicity the operation of tapping the cephalo-rhachidian liquid.

*Accidents.*—Matters, however, do not always terminate so happily. Obstacles may be met with; accidents may occur which the practitioner should bear in mind. At first, although the different

parts of the operation may have been followed with care, it may happen that no liquid flows out. There has been a "miss." The reasons for this disappointment are various. Instead of piercing the membranes, the needle may have pushed them before it, making a cap of them, so to speak, as has sometimes happened in thoracentesis for pleurisy, or that the needle, having gone too far, penetrated the cauda equina and was not consequently in the cul-de-sac. To overcome these obstacles it is generally only necessary to insert farther or to withdraw the trocar or give it a certain rotary movement. A small clot of blood may block the instrument. In such an event aspiration may be made with a Pravaz syringe. Sometimes also it occurs that the liquid will not come out by reason of want of pressure. By making the patient cough, this accident is remedied.

Besides these accidents, which constitute a simple *contretemps* in the operation, there are others deserving attention. Blood may issue instead of the cephalo-rhachidian liquid by reason of a vein being wounded by the needle, and this sometimes persists. In such case the trocar may be withdrawn and inserted in another place. Care should be taken not to push in the needle too far. M. Abadie recommends one inch in children and two to three inches in adults. After the operation, the patient may complain of rhachalgia; staggering gait, vertigo, convulsions and a rise of temperature have been observed more than once.

Generally speaking, all these phenomena possess but little gravity. Simple rest in bed is sufficient. The same might be said of vomiting, sometimes observed. Attention, however, should be paid to the cephalalgia, which is rarely absent after this operation. It is a sensation of weight accompanied by lancinating pains lasting from a few hours to three or four days. Frequently it is very painful, so that the patient is obliged to remain motionless in bed. It disappears, however, without leaving any trace. Sudden death has been observed after puncture of the cord. This unfortunate termination is announced by a violent headache, respiratory troubles, precipitation, weakness and irregularity of the heart beats, in a few moments the patient falls into coma, the breathing stops and no artificial means are capable of re-establishing it. In the statistics of Gumpecht, seventeen cases of sudden death are registered. It must be said, however, that this accident occurred only in subjects affected with grave lesions of the brain (tumours, ventricular congestion), and in cases where the quantity of the cephalic fluid removed was considerable (two to three ounces). This fatal accident is considered due to a too brusque decompression of the nervous elements. To avoid it,

only a small quantity should be withdrawn, from one to two drachms.

*As a Therapeutic Means.*—When Quincke imagined the lumbar puncture, his idea was to act against affections producing a hypersecretion of the cephalo-rhachidian liquid and an excess of pressure in the cerebro-spinal arachnoid cavity. He practised numerous punctures and others followed his example, but the results have been so contradictory that it is impossible to say if the operation can be considered as capable of rendering real service. We have got no farther than that. In congenital hydrocephalus, the lumbar puncture has replaced that of the lateral ventricles. Repeated tapping, withdrawing from an ounce to two ounces of the liquid, have been practised. Generally, the immediate result is very good, the convulsions disappear, the limbs recover their movements, the sight is improved as well as the psychic functions. But this improvement does not continue, the patient gradually relapses into his former condition. Quincke and Stadelmann have concluded that the operation had little or no effect on the disease. In certain subjects affected with cerebral tumours, it frequently happens that hypersecretion of the cephalo-rhachidian liquid produces compression on the brain and the medulla, provoking headache, optic neuritis, stupor, and epileptiform convulsions. Lumbar puncture has relieved some of these symptoms and might be tried.

In all the varieties of meningitis the operation has been tried in a systematic manner. According to M. Abadie it gives excellent results in that variety which Quincke mentioned under the name of simple serous meningitis. In several cases of syphilitic meningitis it relieved the first symptoms, giving time for the specific treatment to act. But in tuberculous meningitis the results are very contradictory—*nil* in some cases, transitory in others; while in a few they were very encouraging. The headache, which is a very distressing symptom, generally yields to the operation, and for this reason one would be justified in having recourse to it.

Acute uræmia has been also treated by the lumbar puncture. Two typical cases of Dr. MacVail have been already published. Two patients, suffering from the convulsive and comatose form of uræmia in the course of Bright's disease, were cured by the operation. These patients had been already treated by injections of pilocarpine and applications of hot air, but without success. An ounce of the cephalo-rhachidian liquid was drawn off, and under the influence of this intervention the coma yielded, the patients recovered consciousness and the convulsive seizures ceased. On the other hand, the œdema gradually disappeared and the albumin diminished, while the quantity of urine increased.

But the lumbar puncture is not only employed to evacuate simply a certain quantity of cephalo-rhachidian liquid, it is utilised also to introduce therapeutic agents into the subarachnoid spaces, especially since Sicard proved that absorption by this means was superior to the subcutaneous method. In patients affected with tetanus this author injected antitetanic serum, chloride of sodium, to a man suffering from general paralysis, and bromide of potassium to epileptics. Injections of cocaine beneath the arachnoid membrane to produce anæsthesia were imagined by Bier and vulgarised by Tuffier. Many surgeons tried this

method, but with different results, and finally, through grave accidents, it was abandoned.

*Lumbar Puncture as a Means of Diagnosis.*—The lumbar puncture allows the cephalo-rhachidian liquid to be studied in all its characters—chemical, physical, bacteriological, and cytological. In the normal condition, this liquid is clear, colourless, limpid as running water, and gives no deposit when at rest. These different characters can be considerably modified. If the liquid can remain clear in cases of hydrocephalus or of hypersecretion consequent on a cerebral tumour; if it can issue clear but becoming clouded on rest in tuberculous meningitis; if it is discoloured at the outset in coccic meningitis and absolutely purulent in suppurating meningitis, coloured red in fractures of the skull and in a large number of cases of traumatism of the cranium. The bacteriological examination has given the following results: in the normal state the liquid contains no microbe, but in coccic meningitis are found streptococcus, staphylococcus or the pneumococcus; in cerebro-spinal meningitis the diplococcus of Weichselbaum, in tuberculous meningitis the bacilli of Koch, but not always.

The importance of the demonstration of these different agents in the liquid obtained by the lumbar puncture is very considerable as it permits diagnosis of the existence and nature of the meningitis.

*Conclusions.*—From what has been already said tapping in the lumbar region is an operation of easy execution, and if done with care and not too much liquid is withdrawn no accidents will occur. The operation has not given as yet any curative results in the treatment of the different maladies for which it has been employed. But it has afforded important relief to some symptoms—headache, certain pains and cerebral accidents in some cases of uræmia.

In rendering possible the study of the different characters of the liquid in morbid affections, the lumbar puncture is a means of diagnosis, precise and useful in the different cases of meningitis, especially that of a tuberculous nature.

## EDUCATION UNDER THE MIDWIVES ACT. (a)

By EWEN J. MACLEAN, M.D., M.R.C.P.Lond.,  
F.R.S.Edin.,

Lecturer on Midwifery at the University College of South Wales and Monmouthshire; Senior Gynaecologist to the Cardiff Infirmary; Consulting Gynaecologist to the Porth and Mountain Ash Cottage Hospitals.

PRACTICALLY alone among civilised and progressive countries England, until quite recently, has been without a system of registration and supervision of midwives. France, Russia, Sweden, Germany, and Switzerland have long paid much attention to the education and State control of midwives. In Japan the regulations for midwives are very strict. No midwife may attend a case unless she has the *Japanese* certificate. Their written examination lasts four days. When a midwife attends she is supposed to take a pupil with her, so that practically two nurses attend every case. It is true that attention has for many years been called to this anomaly of ours, and since 1890 several Bills have been presented to Parliament, some even passing a second reading; but not until 1902 did a measure dealing with the subject receive the Royal assent.

(a) Inaugural lecture of the Course of Lectures to Midwives, delivered at the University College, Cardiff, on October 24th, 1904.

The delay in legislation has certainly not been due to any lack of material to which that legislation might apply, for it is estimated that throughout the country no fewer than 500,000 women annually are attended by midwives. Probably 33,000 are so attended in South Wales and Monmouthshire.

In *France*, where some form of registration is traceable as early as 1292, the municipalities have taken strong measures to enforce education and supervision of midwives. In *Italy*, where special regulations were issued in 1890, the mortality from child-birth and child-bed has fallen from 235 per million in 1887 to 85 in 1902. In our own country during the same period the mortality has not even fractionally improved. It is estimated that in every ten years we lose 46,000 mothers in child-birth, and half of this appalling total of deaths is caused by puerperal fever—a disease for the most part preventable. The average mortality from puerperal fever and accidents of child-birth for England and Wales was 4.7 per 1,000 births; for London, 3.9; while that for South Wales was as high as 6.1.

But it may be asked whether these high mortality-rates have any special reference to midwives. The assertion is rendered probable from the fact that an average proportion of 60 to 70, or even in some districts as many as 90, per cent. of the confinements are attended by midwives. It is rendered practically certain when we remember that in lying-in institutions, where vastly improved methods are in vogue, the child-birth mortality has been markedly reduced. In other words, the practice of the midwives, which covers so overwhelming a proportion of the labours throughout the country, has not been brought into line with the more enlightened methods which the advance of science has placed in our hands.

Let it be emphasised here that there *can* be no attempt to abolish the calling of the midwife. Midwives are a necessity for the poor, and for many of the mothers of the working classes who cannot afford a doctor's fee. The advantages of instruction and supervision should long ago have been placed within her reach, and it is in order that malpraxis may be checked and that effective knowledge may be added to kindness of service that this new legislative measure has been brought into operation. The practice of existing midwives must be levelled up and those who intend to follow this calling must now show evidence of at least a moderately efficient training and knowledge.

The Midwives Act has formulated a central authority in London and throughout the counties and county boroughs of England and Wales, local authorities, for the purpose, as stated in the preamble, of securing "the better training of midwives and to regulate their practice." The central authority, known as the Central Midwives Board, is charged with the carrying out of all the provisions of the Act with the approval of the Privy Council. These duties include the regulation of the course of training of midwives, the issue of certificates after examination, the annual publication of a Midwives' Roll, and the regulating, supervising, and restricting within due limits the practice of midwives. The Act, it may be here noted, applies only to England and Wales.

After April 1st, 1905, no woman will be able to style herself a midwife unless certified under the Act. The penalty is a fine not exceeding £5. After April 1st, 1910, no woman will be allowed to practise for gain as a midwife unless certified, under a penalty not exceeding £10. These provisions do not affect the case of one rendering assistance in emergency nor the practice of those attending confinements under the direction of a doctor. Up to March, 1905, claim to be certified may be made by those holding a certificate in midwifery from the Royal College of Physicians of Ireland, the Obstetrical Society of London, the Coombe Lying-in Hospital, and Guinness's Dispensary, the Rotunda Hospital, or such other certificate as may be approved by the Central Midwives' Board. Further, women who can satisfy the Central Board that they have been in

actual practice as midwives for at least one year prior to July 31st, 1902, and that they bear a good character, may claim to be certified under the Act. Those who do not come within one of these categories are required to pass the examination of the Central Midwives Board before obtaining a certificate, and their names will be entered on a separate Roll. The first of these examinations will be held in July, 1905.

But whilst this central controlling board exists, the keynote of the practical efficiency of the Act is devolution. Every Council of a county or a county borough throughout England and Wales is the local supervising authority over midwives. These bodies, however, can delegate their duties to committees or to the district councils if they think proper. Such committees may consist wholly or partly of members of the Council, and women are eligible to serve on the committees.

The local authorities appoint an executive officer, and the medical officer of health is, from his position and knowledge of administration, eminently fitted to serve in that capacity. In the great majority of instances, the medical officer of health has been so appointed.

The local authority exercises general supervision over all midwives practising within the area of the county or county borough, and has to investigate charges of malpractice, negligence or misconduct, and report the same to the Central Midwives Board.

Every certified midwife must, before commencing to practise, give notice in writing to the local authority of her intention, and must repeat the notice in January of each year during the period in which she continues to practise. She must give every facility to the local authority, and their executive officer, for carrying out supervision, and she will be prohibited from engaging in any unhealthy occupation.

Dr. Ward Cousins, of Portsmouth, in an interesting paper on the Midwives Act, (a) notes that in Sweden the midwife has to be examined every year by the medical officer of health, and should her knowledge be found deficient on any material subject, she can be suspended from practice for a time.

Under the Act, the midwife is permitted to attend normal labour only, and she is compelled to send for a qualified registered practitioner in every emergency. The course of training and the subsequent examination will deal specially with the recognition of danger and abnormality in either mother or child.

The midwives in *Switzerland* are required to make a solemn affirmation on receiving their certificates. They promise on oath to practise their profession with reverence, patience, and earnest endeavour, and, on every occasion, to send for a physician in all abnormalities. For exceeding her sphere of practice the midwife is liable to a fine of from 10 to 1,000 francs.

Under an Act, upon the medical man who is called in by the midwife upon the occurrence of certain symptoms falls the duty of notifying puerperal fever and other infectious disorders. The midwife does not diagnose the disease, but sends for the doctor. Information of all cases of fever should be forwarded at once to the local supervising authority. The record of the midwife will show the number of cases which have occurred in her practice and the name of the doctor who assisted her.

After any attendance upon a case of puerperal fever or any other disease supposed to be infectious, the midwife must disinfect herself and her appliances and have her clothing thoroughly disinfected before going to another case, and the local supervising authority may suspend a midwife from practice if suspension appears necessary to prevent the spread of disease.

Dr. Ward Cousins, in the address from which I have quoted, says: "I believe that the work of the midwives in promoting reform in the houses of the poor will have a wide and wholesome influence. . . . I think it is not too much to hope that indirectly the silent work of educated midwives will prove a wholesome

(a) Annual meeting of the British Medical Association, 1903.

stimulus to the higher classes of society and arouse their sympathy in the great work of improving the dwelling-houses of the labouring classes of our country.

From the foregoing short statement it is evident that the efficacy of the measure will depend in large part on the thoroughness with which the various local supervising authorities carry out its administration; and, further, whilst many strict regulations as to supervision and practice are given, much is left to local initiative in providing the education needed for the new class of midwives which the Act will create. It will be appropriate here to remind midwives that it will be to their interest to acquaint themselves fully with the new conditions under which they must now work. It is not enough for them to become certified merely and to continue to practise on the same lines as heretofore. They should consider the advisability of attending a course of lectures where their duties are taught and their responsibilities defined. The Central Midwives Board include this as an important section in a recognised course of lectures. The executive officers of the various local authorities are doing all in their power, by printed notices and other literature, to bring these points under the notice of midwives.

As to the training of pupil and of practising midwives who wish to bring themselves into line with the standard of knowledge required by the Act, various centres are being established. Birmingham and Manchester, for instance, are building large maternity hospitals to which out-patient departments will be attached.

As to our own locality, the course of lectures we inaugurate to-day is the outward and visible sign of the determination of the supervising authorities of the county and borough to deal with the problem of the efficient education of midwives. It is to the point to say that if that problem be solved in South Wales, it may be solved anywhere. It is appropriate, therefore, that we should be the first in the field, for this course of lectures in connection with the medical faculty of the University College is the first of its kind in the Kingdom. Its establishment has met with the warm approval of the Central Midwives Board, and others are likely to follow the example.

In January of this year, Dr. Walford, the able medical officer of health for the county borough, in a paper on "The Local Administration of the Midwives Act," suggested that steps should be taken to form a local training centre for midwives. The suggestion was acted upon, and the Committee formed in connection therewith were supported by Principal Griffiths, by Dr. T. H. Morris, Chairman of the County Education Committee, and by Professor Hepburn, Dean of the Medical Faculty, and the course was made conditional to certain financial grants, and those who are most concerned—namely, the working classes and the poor—will be grateful for the public spirit shown by the contributing councils. The Glamorgan County Council make an annual grant of £100 and have the power to nominate twenty-one candidates for free studentships. The Cardiff County Borough Council give a grant of £50 per annum and claim the nomination of nine free students.

When we turn to discuss the practical training we are met by an aspect of the question which is not without difficulty. A candidate for examination must bring evidence not only of having attended a recognised course of lectures, but also of having attended personally twenty cases under the supervision of a qualified practitioner or of a certified midwife recognised by the Board or in connection with a recognised institution.

The question will naturally be asked, How, when, and where may this experience be obtained? Unless the change from the old order to the new is to be a more gradual process than the provisions of the Act would lead one to suppose, it is clear that all available cases must be utilised. In all probability the busy qualified practitioner will have little time for the necessary supervision. The bulk of the certification as to attend-

ance on cases will be effected by recognised certified midwives and by institutions. It would, of course, be desirable that qualified medical practitioners should give the time for supervision, but the probabilities do not lie in that direction.

Doubtless, in course of time, and in pursuance of the law of supply and demand, midwives vested by the Board with the power of certification will become established in the outlying districts, but pupils desirous of becoming eligible for examination within a reasonable period of time will naturally seek their experience in the more populous centres and large towns. The rural districts, however, will assuredly supply a considerable number of the cases.

In this connection it is permissible to refer to the fact that the Cardiff and District Branch of the Q.V.J. Institute have already added a maternity department to their work. That department will be recognised by the Central Midwives Board for the practical training of pupil-midwives. The cases will be attended under the supervision of experienced certified midwives and of the Superintendent of the department.

It is anticipated that in January of next year, *i.e.*, in three months time, the department will be separately housed and ready to undertake the practical training of a certain number of non-resident and of resident pupil-midwives.

Such, in outline, is the information which, up to the present, I am able to put before you. As we are practically the first to carry a scheme of the kind into operation, our work and experience will be watched by other centres in the country, and those of us who are associated in the educational aspect of the Midwives Act are resolved that no effort on our part shall be spared to give the best possible effect to the provisions of a measure which so nearly concerns the welfare especially of the working classes and the poor, and also, in a wider sense, of the community as a whole.

## A COMBINED UTERINE APPLICATOR AND BLUNT CURETTE IN GYNÆCOLOGY.

By ALEXANDER DUKE, F.R.C.P.I.

For those gynæcologists who prefer the application of liquid escharotics to the cervical canal and uterine cavity, as in cases of cervicitis, chronic endometritis, &c., the instrument depicted will, I think, be found useful, combining two instruments in one, and devoid of the defects common to all other "applicators" with which I am acquainted. The illustration represents a combination of my "cervical curette," designed for the removal of cervical mucus and various secretions filling up and hanging from the cervix and os, with the ordinary probe or applicator, not to be used by wrapping cotton wool round, but as a sliding piston to compress cotton wool, or bit of round lamp-wick placed in cage.

After the use as curette (A) and when well cleansed, the cage is unscrewed, and a piece of either absorbable cotton wool or round lamp-wick inserted; the cage is then screwed on, dipped in the escharotic

chosen and introduced into the uterus. The pressure of thumb and support of fingers on side-rests will push up central rod and the contents of cotton wool or wick be extruded where required.

Advantages claimed — (1) Surface cleaned by the curette (rotary action) prepares it for the application of the caustic (which is not, as often happens, absorbed by discharge or squeezed out by contraction of cervix on armed probe alone, and so practically useless); (2) no fluid can be squeezed out of cotton wool or lamp-wick by contraction of cervix, the wire cage effectually preventing this; and (3) free exit for any excess of caustic fluid during withdrawal of applicator, the contents of cage just mopping surface; no dribbling if contents of cage be properly charged. By the use of my combination instrument the cure of chronic endometritis, &c., will be hastened, the choice of escharotics being left to the judgment of the operator, as each case must be treated on its own merits.

## NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS.

By DAVID WALSH, M.D. Edin.,

Senior Physician, Western Skin Hospital, London, W., &c.

OF recent years there has been a marked tendency to lessen the use of drugs in the treatment of not a few diseases. As we all know, many complaints formerly treated by physic are now forthwith handed over to the operating surgeon. In a host of other maladies the medical man nowadays turns for aid to physical methods, such as the "high frequency" electrical current or hot air baths, or to the old-fashioned remedies of good food, travel, exercise, pure air, and sea-bathing. In the present article the chief point that will be dealt with is that of food-nutrition in relation to wasting disease.

The subject was suggested to the writer by various medical friends, who reported excellent results in such cases from the use of a particular food, Sanatogen. On inquiry, I found that the nutrient product in question had, during the past five years or so, been extensively used in Germany, where it had been favourably spoken of by many eminent men, including Professors Ewald, Tobold, Neisser, Walther, von Schroetter, Duhrssen and others. Their results, published in various medical journals, were so remarkable as to suggest a kind of specific nutrient value in this new food. On further reference I found that Sanatogen was being advertised in the *Lancet*, *British Medical Journal*, *Medical Press and Circular*, and other leading professional journals. There could be no doubt, therefore, as to its acceptance and standing in the medical world. At the same time it seemed desirable to learn more as to its qualities by a systematic clinical investigation. Accordingly, it was determined to put the matter to a careful trial. This has been done in a series of selected cases, some of them taken from private and others from hospital practice, in which all details have been accurately noted. My results, briefly stated, have confirmed those of the above mentioned Continental observers. They have been sufficiently striking to warrant the belief that in Sanatogen we have a nutrient food of more or less specific absorbability into the system,

and hence of considerable nutritive value in all cases of acute or chronic tissue starvation.

The composition of Sanatogen is stated to be 95 per cent. of pure casein (milk albumin) with 5 per cent. of glycerophosphate of sodium. Many foods have [an apparently equal nutritive value, but every medical practitioner knows how difficult it is to nourish a patient suffering from disease-emaciation. The wasted body remains wasted in spite of abundant feeding with eggs, milk, peptonised foods, meat extracts, and the round of invalid diet. Do we not all recognise the fact that the starving tissues are fed, not by the food swallowed by the patient, but by the amount of nutrient matter absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood, the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. Failing that somewhat remote contingency, it is conceivable that some way may be found of preparing a foodstuff as to render it readily absorbable in the alimentary canal, no matter how disturbed and weakened the digestive functions may have become. Judging from clinical results, Sanatogen appears in many cases to possess some such power of ready absorbability, without which the richest foodstuff represents simply so much foreign matter in the stomach and intestines. My own experiences are here recorded as a simple extension and confirmation of the remarkable statements of the distinguished Continental authorities already cited. It is to be hoped that medical men here in the United Kingdom will ascertain for themselves the value of this dietetic remedy in wasting diseases, in convalescence, and, indeed, wherever there is evidence of general malnutrition.

A certain number of the cases experimented upon were those of wasting children, or "wasters," as they are technically called. One of the greatest difficulties with which the physician can be faced, either in hospital or in private practice, is to restore the general nutrition of these little patients. In spite of the utmost care in the regulation of diet the mortality among these children is extremely high. The wasting is obviously a sign of defective nutrition, and the loss of body-weight persists regardless of the quantity or quality of the food introduced into the stomach.

The explanation is probably that nutrient matter is not absorbed because of some atrophy or imperfect development of the structure or functions of the glandular and absorptive apparatus of the stomach and intestines. Wasting from insufficient food may be taken as the simplest form of infantile atrophy. General tissue starvation may also be due to the taint of tubercle, especially in the form of *tabes mesenterica* or of syphilis. Rickets is another predisposing cause, although, happily, it is becoming much less frequent nowadays. Other causes, again, are "fevers" and various invasions by pathogenic organisms.

The prominent symptoms of almost all forms of infantile wasting are, diarrhoea, vomiting and anæmia. The chief point about the *wasting* is its persistency—repeated weighing reveals no increase in weight. The *diarrhoea* is a constant symptom, with stools that are as a rule green and offensive, but at times they are yellow with greenish streaks. The *vomiting* is persistent and

urgent, and occurs immediately after food of any kind whatever. The *anæmia* is characterised by erythrocytes of not more than two millions to the cubic millimetre, while the *leucocytes* are increased to, say, 12,000, and the hæmoglobin value may be anything between 36 and 64 per cent. These patients are apt to get pneumonia, usually of the broncho-pneumonic but sometimes of the lobar variety.

In looking for the cause of infantile wasting with the above train of symptoms, the physician will naturally note any past or present evidence of "snuffles," rash, delayed closing of fontanelles, or of any of the various bony or glandular changes associated with tubercle, rickets, or syphilis. Whether specific drugs be or be not required, it goes without saying that dietetic treatment must always be of first importance in such conditions. My own experience of Sanatogen, as shown in the appended cases, is that it stays the diarrhoea—ten or twelve motions a day are thereby reduced to one or two; it stops the vomiting, and it improves general conditions and causes the patient to put on flesh. Finally, it brings about some amount of improvement in the coloured corpuscles, which increase at the rate of about 10,000 per c.mm. daily. These results, due, as I believe they are, to such simple means, are worthy of the careful attention of every medical man who is called upon to deal with wasting diseases.

*Case I.*—A. B., male child, æt. one month; brought to hospital with a history of diarrhoea, vomiting and wasting from birth. There were usually from eight to ten green, slimy and offensive motions in the twenty-four hours. The child had "snuffles," and was covered with a syphilitic rash all over the body. It was breast-fed, but a little cow's milk diluted with one-third lime water had been given from time to time. The weight was only 4½ pounds. Treatment included grey powder, inunctions of mercurial ointment, and the administration of subnitrate of bismuth, both in small and in large doses. The incessant vomiting, however, went on unchecked, and, humanly speaking, there seemed to be not the least chance of recovery. At this point all medicinal treatment was discontinued, and the infant ordered a teaspoonful of Sanatogen in a mixture of milk and cream every four hours. This combination was taken well, and in less than twenty-four hours the vomiting and diarrhoea had ceased. The child gained half a pound in weight in a week, and made a good recovery.

The foregoing case speaks for itself. It has an extremely suggestive value as regards the relation of general nutrition to the curative action of specific drugs upon the body. The following case illustrates the use of Sanatogen in stopping diarrhoea and vomiting in a wasted child, where there was no evidence of any specific disease.

*Case II.*—C. D., a female child, æt. four months; brought with a history of almost continuous diarrhoea since birth. There were many motions daily, of a yellow colour streaked with green, and very offensive. Milk, cream, and many kinds of "infant foods" had been tried in vain; nearly all of them excited vomiting. The child weighed only six pounds, was thin and pale, with an irregular temperature ranging between 98° and 101°. There was no evidence of syphilis nor of tubercle. The red blood corpuscles numbered 4,150,000, the leucocytes 11,000, whilst the

hæmoglobin value was 61 per cent. Sanatogen given in two-drachm doses every four hours promptly stopped the diarrhoea and lessened the vomiting. In four days the temperature had fallen to normal, and at the end of a week the red cells had risen to 4,230,000 and hæmoglobin value to 62½ per cent. The treatment was continued for some time, and careful weighing showed that the child gained weight at the rate of about a quarter of a pound a week.

The following cases show the value of this new form of food nutrition in various wasting conditions:—

*Case III.*—F. F., female, single, æt. 18, waitress in a London tea-shop; complaining of palpitation and shortness of breath. For three years she had suffered periodically from attacks of *anæmia* and amenorrhœa. She was liable to fainting fits, especially when actively engaged in a hot room. The conjunctivæ and the mucous membrane of the lips were pale. Her red blood corpuscles numbered 3,500,000 per c.mm., with a hæmoglobin value of 42 per cent. She lived chiefly on tea and bread and butter, and it was only with much difficulty she was able to continue her employment. After relief of constipation she was ordered Sanatogen in milk as a staple article of dietary. This she took without difficulty, and in a fortnight her red cells improved at the rate of 10,000 a day. Her symptoms gradually subsided, and at the end of a month she was able to take her meals with a good appetite, and was free from all appearances of *anæmia*.

*Case IV.*—G. H., a married woman, æt. 36, suffering from melancholia. She had sustained a severe shock from the sudden loss of her favourite child. She took to her bed and practically refused all food with the exception of beef-tea, milk and jelly. She lost weight rapidly, and suffered from profuse sweating at night. No sign of tubercle, however, could be detected in the lungs or elsewhere. She was *anæmic*, and her red corpuscles numbered only 3,800,000 per c.mm., with hæmoglobin 48 per cent. She was placed on Sanatogen, and at once began to improve. Her mental equilibrium was restored, she developed fresh energy, and at the end of a fortnight was able to resume her home duties. Her red cells had by that time risen to 4,000,000 per c.mm. and the hæmoglobin to 52 per cent. The improvement in this case was most striking and suggestive.

*Case V.*—T. J., an elderly widow lady, had suffered for many years from chronic bronchitis and emphysema. Of late she had developed glycosuria; the amount of urine passed in the day measuring on an average six pints, with a specific gravity of 1025. She lost little flesh and there were no other symptoms of diabetes. She had been carefully dieted by a physician, under whose direction all sugar and starch were excluded. Unfortunately, from the state of her teeth she was unable to masticate the various substitutes for bread which were from time to time suggested. Her heart was dilated, and she suffered much from dyspnoea on exertion, even when the latter was slight, such as going slowly upstairs. Flatulence was another great trouble, and eructations were almost incessant. The dietary was relaxed, and she was placed on one-ounce doses of Sanatogen in milk every four hours. In less than a week all her subjective

Symptoms had disappeared, and the urine was free from sugar. Her powers of walking gradually returned, and in a month she was able to walk half a mile on level ground twice a day without much inconvenience.

*Case VI.*—K. L., a girl, æt. 3, brought to me by her mother for advice on account of "weakness." Family history good; child fairly well nourished; had enteritis of four weeks' duration when one month old, and bronchitis lasting three weeks with two convulsions at the age of one year. Has always been "delicate" and nervous; cannot walk far, as she complains of pain in her knees. Teeth good; moderate "knock-knee"; height  $37\frac{1}{2}$  inches; weight  $32\frac{1}{2}$  pounds (fifteen months previously 32 pounds). No organic or constitutional disease was found. The only suspicious point was the almost stationary weight, which in an ordinary healthy child of her age should clearly have increased many pounds in the course of fifteen months. She was ordered Sanatogen, one teaspoonful twice daily, and at once began to put on weight at an average of half a pound weekly. The error of nutrition, in this instance of obscure origin, appears to have been effectually remedied by a simple dietetic treatment.

*Case VII.*—M. N., a gentleman, of middle age, who had suffered for eleven months from epithelioma of the soft palate. About the second week in September, 1904, he had reached an extreme stage of emaciation, and had taken for several weeks to his bed, from which he had before that time been carried downstairs in a chair. Sanatogen was ordered in teaspoonful doses twice daily in milk. A marked improvement in the general condition rapidly followed. The hollows in the cheeks and temples became much less visible, and after a time the patient actually walked downstairs, and interested himself in painting picture-frames and so on. More striking still was the fact that he several times asked for and ate a boiled egg, although he had taken nothing but "spoon" diet for months previously. In this case Sanatogen produced a distinctly favourable effect on the general nutrition and condition. The improvement was far more marked than happens in the occasional "turn for the better" met with in most cases of malignant disease, and lasted for many weeks.

Although I have had no experience personally of the use of Sanatogen in convalescence from enteric fever, a medical friend has found it invaluable under those circumstances. Anything that can help one to tide over the anxious period of typhoid convalescence will be sure of a warm welcome by medical men. For many years it was the invariable rule both in hospital and in private practice not to give any food beyond milk, cream, and beef-tea until the temperature had been normal for ten days. During that time of probation patients craved for food incessantly, and suffered much distress from restless nights and from the pangs of hunger. This rule was gradually relaxed; first coffee and then mashed bananas and cream were allowed, and the time of probation shortened. It is now admitted by many good authorities that solid food may be given in milk after the fourth day of normal temperature with absolute safety. The comfort of the patient is thereby much increased, and his convalescence shortened. In this and in the

other conditions above mentioned, Sanatogen deserves a careful trial by medical practitioners, as a readily assimilable form of semi-solid food. It is readily prepared, moreover, a point of some importance in the sickroom.

On the Continent, Professor Ewald (a) has spoken warmly of the value of Sanatogen in enteric fever. He administered that food to a patient on the fifth day after admission to hospital early in the third week of an attack of typhoid fever. As the result of experimental investigations he concluded that Sanatogen is valuable, on account of its ready absorbability, in all cases of physical weakness, "as well as in the acute stages of all those maladies which are accompanied by high rise of temperature and particularly in enteric fever." Dr. Eduard Rybiezka (b) advocates the use of the same preparation in convalescence from the malady in question.

*Case VIII.*—A lady, æt. 50, single, complaining of stiff joints and wasting. Her mother died of phthisis, also a brother. When young she had an attack of St. Vitus' dance, after falling downstairs. Between 20 and 25 she suffered from chronic cough, and was treated for incipient consumption. General health had been good ever since, and she had been of active habits, and took a great deal of outdoor exercise. Seven or eight years ago her hands began to get stiff and painful, and later the feet, elbows and knees were involved. The hands showed the typical deformities of advanced osteo-arthritis; the fingers were enlarged at the joints, and those of the right deflected outwards and clawed; large swellings, both bony and bursal, were present on the backs of hands and wrists. The right hand was worse, as the fingers were partly clawed into the palm and the wrist also partly locked. There were tender spots on the hands, but for the most part tenderness and pain were absent. The feet, elbows and knees were more or less involved; the elbows could not be straightened, and there was a great deal of "egg-shell" deposit about the knees, especially the right. There had recently been a considerable loss of weight, although the appetite remained good. A careful search failed to reveal tubercle in the lungs or elsewhere, and no disease of heart, kidneys, or other organs accounted for the loss of weight. This patient was treated by the super-heated air method, introduced and perfected by the late Mr. Tällerman. The joints soon gained in power of movement, and the joint swellings diminished rapidly in size. At the same time the general health improved greatly. Sanatogen was ordered at the outset in teaspoonful doses twice daily. The patient was first seen on October 11th, when she weighed 6st. 9lbs. Sanatogen was first given on the 14th in teaspoonful doses thrice daily, increased gradually to two teaspoonfuls. The weight began to increase at once, and on October 28th the weight was 6st. 11lbs.

This case shows the value of a readily absorbable food in the perverted nutrition of a general disease like osteo-arthritis. The great loss of weight is met with occasionally in cases of rheumatoid arthritis in which there is no gross organic disease. A well-known physician has recently published several cases of extreme wasting in

(a) *Zeitschrift für diätetische und physikalische Therapie*. Von Leyden. Article by Dr. C. A. Ewald.

(b) *Wiener klinische Wochenschrift*, 1900, Vol. ix.

connection with pulmonary osteo-arthopathy. In my experiences the joint changes in these cases are the essential feature, and the thoracic trouble an accidental complication of more or less severity. For some years past I have had a large experience of osteo-arthritis cases at the Tallerman Free Institute. Scores of chronic osteo-arthritis or rheumatoid conditions were seen; a fair number, perhaps 25 per cent. of them, showed marked wasting, but I can recall only two or three in which there was serious advanced disease of heart or lungs. At the same time slight valvular murmurs were common enough, as might be expected from the frequent history of rheumatic fever in osteo-arthritis cases.

(D. Walsh.)

RADIOGRAM OF HAND IN CHRONIC OSTEO-ARTHRITIS.

It may be of interest to insert here a radiogram which I have taken of the left hand of this patient. It shows in various joints—as about the phalanges and wrist—the typical light bony outgrowths near the articulations, with destruction of cartilages and partly of epiphyses well seen in the first and fourth metacarpo-phalangeal joints. These appearances differ markedly from the bone changes in chronic gout, where parts of the bones are cut out sharply as if by a gouge. The thumb is dislocated from the metacarpal bone and its metacarpo-phalangeal joint is disorganised. The styloid process of the ulna is hypertrophied (it is tender to pressure). The wrist bones generally are obscured by effused material. The figure is a good specimen of the condition of bone met with in rheumatoid or, as it is nowadays more commonly called, “osteo-” arthritis, while the typical fusiform thickening of the fingers in that disease is particularly well shown.

## Clinical Records.

### NORTH-EASTERN HOSPITAL FOR CHILDREN.

#### *A Case of Infantile General Paralysis of the Insane.*

By GEORGE CARPENTER, M.D.,

Editor of the *British Journal of Children's Diseases*, Late Physician to the Evelina Hospital for Sick Children; Senior Assistant Physician to the North-Eastern Hospital for Children.

ELIZABETH C., æt. 11 $\frac{1}{2}$  years, was admitted into the North-Eastern Hospital for Children in July, 1903. It was stated that she was in perfect health until April, 1902, when she was lost for a night, and ever since then had been “queer in the head.” She has gradually been getting worse mentally ever since, being obstinate and screaming on the slightest provocation. There has been occasional frontal headache; she has slept badly and taken her food badly; she has never had any fits or seizures; ten years ago she had measles. There is no family history of insanity. Several healthy children were born to the parents. Next a child was born dead, this was followed by a living child, then the patient, and lastly a boy of eight years, who is suffering from nerve deafness in both ears.

*State on Admission.*—She has an unusually thick covering of subcutaneous fat, and her skin is natural. Mentally she has two well-defined states. She lies awake most of the twenty-four hours, and talks incoherent nonsense to herself quite quietly and oblivious of her surroundings. Such remarks as “The goldfish are very happy,” “No, Bobby is all right,” and so on, can be heard by those standing by her cot. During this her face wears a placid, self-pleased expression which calls to mind the fatuous type of the general paralysis of the insane patient.

On being crossed by contradicting one of her statements, or by disturbing her physically, she bursts into an attack of loud screaming and weeping, which lasts for a few hours. She will usually answer simple questions, and is obedient to such demands as putting out the tongue until this sudden storm be evoked. She has hallucinations of pleasant objects, such as flags, ladders, and bowls of water, which are quite common. Auditory and olfactory hallucinations have not been noticed. She continually mocks other children's cries or street cries, and imitates them well. She does not know her mother.

Her arms and legs are moved well, the former better than the latter. She can walk, and there is some slight spasticity of the lower limbs. There is a flickering tremor of the lower facial muscles when smiling or talking. The tongue is protruded normally, and has an occasional tremor. There is a fine tremor of both hands, which is most marked on first gripping an object. The plantar reflexes show typical Babinski response on both sides. The elbow-jerks are active. The supinator-jerks are abnormally increased. The knee-jerks are very active and equal. There are no clonuses. So far as can be ascertained sensation is unimpaired. Her organs are normal. She cries frequently when the desire occurs for micturition or defæcation, but has deficient power of retention, so that both evacuations are passed involuntarily. Her feet are cold and red, and sometimes blue—she has pes cavus.

She has a long face and depressed bridge of the nose. The facial muscles are generally well

developed, and there is no local wasting. There are no radiating scars about the mouth. She has typical Hutchinson's teeth. Her pupils are equal. They do not react at all to light, and the accommodation cannot be tested. The fundus oculi was examined under an anæsthetic. The optic discs were pale, and there was a small patch of choroiditis in the left eye. Vision was very defective, being lost to all but light. There was no reaction to a threatening movement.

The case is of interest owing to the youth of the patient and from the undoubted corroborative evidences of congenital syphilis associated with that condition.

[Shown to the Society for the Study of Disease in Children, November 20th, 1903.]

### Transactions of Societies.

CLINICAL SOCIETY OF LONDON.  
MEETING HELD FRIDAY, OCTOBER 28TH.

The President, DR. FREDERICK TAYLOR, in the Chair.

#### CLINICAL EVENING.

DR. F. E. BATTEN showed a case of Acute Ataxia in a boy, æt. 3½, due to Encephalitis Cerebelli. Patient had measles in March, 1904. During convalescence he became unconscious, and remained so for a week. He then had convulsions and tremors, and on becoming conscious he could not sit up or speak. A month later he had marked inco-ordination of both legs and arms. There was no paralysis. The knee-jerks were well marked, and a tendency to ankle-clonus. He swallowed well, and spoke in a low, hesitating manner. Since then only slight improvement has occurred. He has complained of "pins and needles" in his limbs. His mother complains that since his illness his moral sense has become much perverted.

The PRESIDENT recalled a case he saw some twenty-five years before, which at the time he considered to be one of disseminated sclerosis, although Dr. Moxon, who also saw the case, did not think so. Now, the case seemed to him to be one of cerebellar encephalitis, almost exactly simulating the one shown. His case completely recovered in two or three years, although there was no diminution in the ataxy for eighteen months.

DR. BATTEN said that on account of Luciani's well-known experiment demonstrating the connection between the cerebellar lobe and the heterolateral cerebral cortex he was of opinion that the cerebral cortex in this case must have been also damaged, thus explaining the non-improvement. He was interested to hear of Dr. Taylor's case, as it would incline him to give a better prognosis in his own.

DR. E. D. MACNAMARA showed a case of Acute Ascending Paralysis; Tetracoccus found in the Spinal Fluid. The patient, æt. 30, a waiter, admitted under Dr. Murrell, August 3rd, 1904, with the history of commencement of loss of power in legs eleven days before, which, within three days, had culminated in absolute palsy. Three days before admission there was weakness of the arms, difficulty in swallowing, and double vision. There is a history of syphilis at twenty-four, which was actively treated. There was on admission total paralysis of the legs except of the right hallux, weakness of the arms, defective articulation and ocular movements, and both pupils were almost inactive to light. No reflexes were obtained in the lower limbs; the other reflexes were normal, as also the electrical reactions. There were no subjective sensory symptoms, nor other objective signs. After August 8th improvement commenced, and has continued. Speech, ocular movements, the pupil reaction, and the arm movements have been recovered. He can move his legs, and the knee-jerks are returning, but he cannot yet walk.

DR. FARQUHAR BUZZARD referred to the tetracoccus he had found in a case of Landy's paralysis last year; the organism was pathogenic to animals, as was shown by Dr. Eyre. The tetracoccus shown that night was not unlike the one he had found, but he could not express a positive opinion on such a slight examination. The different conditions described under Landy's paralysis fell into three groups: (1) The true Landy's paralysis, characterised by sudden general paralysis of all the muscles, though more of the large; a few of the cases get quite well. (2) A type of paralysis equally sudden and disabling, but having the distribution of a peripheral neuritis. (3) Acute ascending meningo-myelitis, marked sensory and sphincter trouble being present.

DR. F. E. BATTEN compared the present case to a toxic paralysis, such as a diphtheritic one. The fact of recovery was against its being due to organisms actually in the nervous system.

DR. MACNAMARA, in reply, pointed out that when Landy's paralysis recovers, it usually does so completely, as one would expect from an acute specific infection. Dr. Eyre was at present testing the pathogenicity of the cultures, but so far had obtained no positive result.

DR. J. H. BRYANT showed two cases, brother and sister, of the Peroneal Type of Family Amyotrophy. The girl, æt. 12, had whooping-cough at four, after which she could not walk properly, and she was treated for infantile paralysis of the legs by orthopædic apparatus. At 5½ she had scarlet fever, and measles at 6 and 8 years. In 1900 wasting of the hands was first noticed, the muscles of the thenar and hypothenar eminences, and the interossei in the upper limb, the small muscles of the feet, the peronei, tibialis anticus, and extensor longus hallucis in the lower limb. The boy, æt. 8, was first noticed to become weak after measles at 2½, his legs frequently gave way, and he could not lift his big toes. When first seen, in 1903, the paralysis of the extensor longus hallucis was the most marked. The paralysis has increased, and the feet are now in a position of talipes equino-varus. A paternal uncle is similarly suffering from weakness and wasting of the legs and hands. His wasting began at the age of three, and he is now bed-ridden.

MR. JACKSON CLARKE showed a case of Hard Fibroma of the Scapula and Spine, in a female, æt. 24. The left scapula was painful, elevated, and fixed by a rounded tumour situated at the middle of the vertebral border. An exploration in May, 1901, exposed a hard, white growth, which hardly bled at all. It filled the subscapular fossa, and was attached to the ribs. As much as possible of the growth was removed. Since this operation the tumour has slowly extended upwards along the spine, causing much pain.

MR. W. G. SPENCER expressed the opinion that the condition might be a spreading fibrous myositis, thus bringing it into line with myositis ossificans.

MR. JACKSON CLARKE was sure that the mass was of new formation, on account of the definite capsule present.

MR. H. A. J. FAIRBANK showed two cases of Sprengel's Shoulder. A girl, æt. 4, had right scapula situated at a higher level than the left; also placed nearer the middle line, as seen when the arms were hanging by the side. The angle of the scapula is rounded off. A band runs from the occiput to the vertebral border. The mobility of the scapula is diminished, as seen when the arms are held horizontally forward. There is no defect in the shoulder-joint or other asymmetry. A girl, æt. 12, has the left scapula at a higher level. The mobility is very much diminished, with muscular weakness, but there is no sign of a fibrous band or bony ridge. The right leg is wasted, apparently from infantile paralysis; the dorsal spine is curved to the left, the lumbar to the right; and the right side of the face is flattened. In neither case is there any family history of such a deformity.

MR. JACKSON CLARKE showed a skiagraph of a similar case. He considered that three factors were essential—spine, rib, and scapular deformity, there being a varying degree of each in a given case.

Mr. RUPERT BUCKNALL referred to similar cases of his own, and discussed the various theories explaining the deformity—such as malposition of the arm *in utero*, primary defects, &c. The ridge passing from the scapula to the spine indicated a defect in the mesoblast, which forms the muscle round the scapula.

Mr. FAIRBANK, in reply, said that, in his opinion, the condition was one of primary defect. In favour of this were the associated defects of the vertebræ and ribs. There was probably a gradation between Sprengel's cases and the cases described by Willett and Walsham, in which a bony mass joined the scapula to the spine. He considered the ridge in his case to be fibrous contraction of the muscle, secondary to the unusual position of the scapula.

Mr. JACKSON CLARKE showed a case of Unilateral Congenital Dislocation of the Hip, reduced by the method of Lorenz. The girl, æt. 7, had a typical displacement at the right hip, which was reduced in August, 1903, as confirmed by a skiagraph. The abducted position was maintained for a year. The child is now walking about without apparatus, with the head of the femur in position. The treatment is not yet concluded.

Mr. NOBLE SMITH showed a case of Unilateral Congenital Dislocation of the Left Hip. A girl, æt. 6½ years, with the above was operated upon by the Paci-Lorenz method in January, 1894. The limb was maintained abducted for six months. The joint is now firm and movable, and the position of the femur is shown in a skiagraph. He also showed a case of Double Congenital Dislocation of the Hip. A girl, now æt. 7½, was operated on by the Paci-Lorenz method in January, 1903, and the abducted position maintained for six months. The joints are now firm and in a normal position, as shown by a skiagraph. The child continues to improve in gait.

Mr. TUBBY asked what evidence there was that the head of the femur was in the acetabulum. He knew of none except by operation. It was well known that a skiagraph of an anterior dislocation, taken at a certain angle, would portray an apparently perfect joint. Many cases reduced by Lorenz's method could be shown to be merely an anterior dislocation instead of a posterior.

Mr. JACKSON CLARKE knew of no such evidence, and even thought that an open operation often failed to decide the point. Actual demonstration of the reduction could only be obtained by watching Lorenz operate. After all, the important point was that whether a true reduction occurred or not perfect function was restored, although some stiffness might follow in the most successful cases.

Mr. NOBLE SMITH, by means of a model, gave a demonstration of the movements involved in mechanism of reduction. He agreed with Mr. Clarke in his remarks on the difference between performing the operation before seeing Lorenz do it, and after.

Mr. A. H. TUBBY showed a case of Ulceration of the Tongue, with Destruction of the Soft Palate, of Uncertain Origin. The affection of the tongue commenced with a hard lump, first noticed in January, 1904. There had been previous deafness on both sides for six months. There is now a rapidly spreading, large, ragged ulcer of the tongue, destruction of the soft palate has occurred, and there is ulceration of the naso-pharynx. There is no history of syphilis, and anti-syphilitic treatment has failed. The microscopic examination yielded negative results.

Mr. CHARTERS SYMONDS was of opinion that the man was tuberculous.

Mr. TUBBY discussed the diagnosis between congenital syphilis, tubercle, chronic glanders, and actinomycosis.

Mr. W. G. SPENCER showed a case two years after Excision of the Sac of a Spina Bifida (Meningo-myelocoele).—A boy, now æt. 2½, was operated upon when six months old. The cauda equina and nerves were dissected out and laid in the groove, which was closed by two rows of sutures. A firm scar now covers the

groove, the legs are used well, and there is no hydrocephalus.

Dr. NEWTON PITT showed a case of von Recklinghausen's Disease. A female, æt. 49, had at birth a tumour to the left of the sternum, and later numerous painless subcutaneous nodules were noticed. New tumours have appeared from time to time, many within the last five years, which at first were firm and prominent, and then, as they increase in size, they become softer. In 1877 Mr. Golding Bird removed a large unencapsuled tumour from the left calf; the tumour on the left chest then formed a pendulous pigmented mass five inches in length. It was removed in 1895, and weighed 3½ lbs. Also in 1877 a raised, pigmented, hairy mole with a molluscum tumour, 4 by 1½ inches, was removed from the right cheek. The patient has now a diffuse fibroid swelling of the left calf, with irregular scarring resulting from the operation; a recurrence of molluscum fibrosus tumours in the right cheek; innumerable raised tumours, from ¼ to ½ of an inch across, scattered over the limbs and face, and, to a less extent, on the body, the skin over them being not generally pigmented. There are no obvious signs of involvement of the large nerve-trunks.

Mr. O. L. ADDISON showed for Mr. A. E. BARKER a case of Lymphangiectasis with escape of Chyle. A man, æt. 20, has a cystic swelling of varying dimensions above Poupart's ligament, and enlargement of the thigh. The disease has been noted since the age of seven years. Chyle escapes from an opening in Scarpa's triangle. If the escape is temporarily prevented by a pad an enlargement occurs in the iliac region. Then the chyle, when allowed, escapes in a stream, and the patient feels relief from tension.

Mr. O. L. ADDISON, replying to questions put by Dr. French, said that the fluid was chylous, and not lymphatic, and so the obstruction must be of the thoracic duct. He drew attention to the fact that the fluid escaped under pressure, spurting to three or four inches, whereas in all the cases previously reported the fluid had only trickled. There had been no suggestion as to the cause of the condition.

The following cases were shown by Mr. CHARTERS SYMONDS:—(1) Simultaneous Ligature of the Common Carotid and Subclavian Arteries for Aortic Aneurysm.

Mr. W. C. SPENCER referred to cases operated on by Mr. Christopher Heath. In those he had seen the results were not good.

Mr. RUPERT BUCKNALL had seen several of Mr. Heath's cases in which good results were obtained. He had himself operated on one case which was rapidly growing. After ligature first of the left common carotid, and then of the left subclavian artery, hardening took place. The man returned to work for two years, then died of phthisis. At the autopsy the aneurysm was found to be healed. He thought that the line of treatment was of great benefit and worthy of wider recognition.

(2) A case of Bony Union after Fracture of the Patella without Wiring.

(3) A case of Popliteal Aneurysm after Ligature of the Superficial Femoral artery.

#### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LIVERPOOL, FRIDAY, OCTOBER 21ST.

Dr. W. J. SINCLAIR, President, in the Chair.

Dr. R. FAVELL (Sheffield) showed a dermoid cyst of the ovary and an ectopic gestation, interesting for the reason that each had had the appendix vermiformis adherent to it. He referred to Howard Kelly's paper on the subject, in which 115 cases are tabulated.

Specimens were also shown by Drs. W. E. FOTHERGILL and MURRAY CAIRNS, and Dr. LLOYD ROBERTS exhibited an improved needle-holder. Dr. E. EMRYS ROBERTS gave a lantern demonstration of the first stage of implantation of the ovum of the guinea-pig.

Dr. ARNOLD LEA (Manchester) detailed a case of

## RUPTURE OF THE UTERUS,

which took place at the seventh month of the fourth pregnancy of a woman, æt. 24. She was admitted to the Maternity Hospital for sudden profuse bleeding due to placenta prævia. Twenty hours after admission a de Ribes bag was inserted into the cervix. Five hours later the pulse had gone up to 124. Dr. Lea arrived at the hospital shortly afterwards and found the patient's condition was good. The bag was removed, and under chloroform bipolar version was performed, the hand not being introduced into the uterus, and a macerated seven months fetus was readily extracted. The patient's pulse then became very rapid, and her skin pallid. The placenta was easily expressed, and the uterus appeared to contract well. A deep tear of the left side of the cervix was sutured. The pulse remained 130 to 134, but the patient was quite comfortable when placed in bed. A quarter of a grain of morphia was given, and also a rectal injection of saline solution with an ounce of brandy. Half an hour later she became suddenly blanched, her pulse failed completely, and she died in five minutes, obviously from internal hæmorrhage. There had been no bleeding *per vaginam*, and the uterus appeared well contracted. An autopsy was made twelve hours after death. The peritoneal cavity contained nearly a pint of blood, which had escaped through a rent in the posterior layer of the left broad ligament. There was a lateral tear three inches in length in the lower uterine segment; this had led to the formation of a huge hæmatoma between the layers of the left broad ligament, and this had ruptured, through a linear rent, into the peritoneal cavity. The uterine muscle was pale, soft and apparently degenerated, and the placental site where the tear occurred was thinned. Regarding the cause of rupture, Dr. Lea said there was a great probability that the patient had had syphilis, her previous children being born prematurely, either dead or dying shortly after birth. The rupture occurred at the placental site, there was no evidence of a retraction ring, the membranes being ruptured shortly before delivery was effected. He thought the rupture probably occurred spontaneously whilst the de Ribes bag occupied the lower segment of the uterus as shown by the rise of pulse to 126. Extraction probably made the tear complete. The three factors in the causation were thus, degeneration of muscle, probably syphilitic; low situation of placenta; aggravation of rupture by version and extraction. The tear was at first incomplete, leading to the formation of a hæmatoma of the broad ligament. Sudden rupture of the posterior layer of the broad ligament permitted free bleeding into the cœlum, and death followed. Discussing the symptoms of this form of rupture, Dr. Lea remarked they were often obscure. In his case there was an absence of all pain, of external bleeding, whilst the uterus appeared by abdominal examination to be firmly contracted. The fetus lay high up, but not more so than normal. In short, the sole characteristic was increase of pulse-rate, and even this, owing to the previous hæmorrhage, had not had sufficient stress laid upon it. Had the tear been recognised immediately after delivery, Dr. Lea said he considered the proper treatment would have been to pack with gauze.

Dr. LLOYD ROBERTS (Manchester) in commenting on the case, thought that everything possible had been done.

Dr. WALTER (Manchester) thought the case illustrated the risk attendant on the use of de Ribes' bag. He had known of two instances in which the bag had disappeared entirely within the uterus. It was important, when employing it, to be quite certain as to the quantity of water pumped into it.

Dr. W. K. WALLS (Manchester) said his experience embraced two similar cases, and he considered that the rupture was due to the delivery and not to the bag.

The PRESIDENT thought it possible that the tear might have occurred during the introduction of the bag.

Dr. LEA briefly replied.

Dr. W. K. WALLS reported a case in which a mass of multiple fibro-myomata of the uterus occupied a large ventral hernia. The patient was married, æt. 44, and the menopause occurred at 35; no pregnancies. History of three operations five years previously, presumably laparotomy. The large ventral hernia contained a solid mass and also fluid; the skin was ulcerated in places; behind the hernia a solid mass extended from pubes to umbilicus. The cervix uteri was drawn up out of reach. At the operation the sac contained about a dozen fibroids varying in size from a hen's egg to an orange. Supra-vaginal hysterectomy was performed and a good recovery ensued. The mass of tumours (shown) weighed 11 lbs.

The case was discussed by Drs. Lloyd Roberts and T. B. Grimsdale, and Dr. WALLS replied.

## LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD OCTOBER 20TH, 1904.

The President, Dr. JAMES BARR, in the Chair.

MR. CHARLES G. LEE read a short paper on the SIMPLE EXTRACTION OF CATARACT BY TEALE'S METHOD.

He briefly referred to the various incisions that from time to time had been adopted, and said that all of these, being placed either behind or at the circumference of the cornea, rendered it almost imperative to excise a portion of the iris. If, therefore, it were deemed necessary to perform an iridectomy as part of the operation, then the better plan is to do it some days or weeks before the extraction, as this method, although it involves two sittings, made less demand upon the patient's self-control, and enables the operator to see clearly each step of the operation, since no blood collects in the anterior chamber, as happens when the iridectomy and the extraction are both done at the same time. The chief objection to this procedure lay in the two operations, and consequently the danger from sepsis was doubled. Having in his private practice last year lost an eye from suppuraction of the cornea, after a preliminary iridectomy, Mr. Lee determined to try if the iridectomy might not be dispensed with as an essential part of the operation. He had himself frequently performed simple extraction, but owing to the incision being placed at the periphery of the cornea, prolapse of the iris had too often occurred. Some twenty years ago he had seen Mr. Pridgin Teale extract cataracts without an iridectomy, by means of an incision wholly in the corneal structure, and almost midway between the centre of the pupil and the circumference of the cornea, so he determined to try this method. Two characteristic features of the operation were insisted upon—the knife employed (Hartley's) and the site of the section. Details of the first eight cases which Mr. Lee had operated upon by this method were given, from which it appeared one patient obtained visual acuity of 6-6, three obtained 6-9, and none less than 6-18. In no case was any difficulty experienced in carrying out the *technique* of the operation. Since these results were obtained by an operator to whom the method was novel, it was submitted that it was well deserving of a trial by all who wished to advance the art of ophthalmic surgery.

Dr. K. A. GROSSMANN said he had performed simple extraction for many years and was well satisfied with the results obtained; but emphasised the importance of carefully selecting the cases suitable for it. He used a knife with a very narrow blade, as he considered the triangular-shaped knife too broad, for it hampered the freedom and delicacy of movement necessary in so delicate an operation.

Mr. GEORGE E. WALKER described an operation which he had performed for upwards of twenty years, which aimed at the same result as that mentioned by Mr. Lee, and which he considered easier of performance. The puncture and counter-puncture are made in the sclerotic, and by a series of sawing movements the incision finishes at a point midway between the centre of the pupil and the top of the cornea. In this operation

prolapse of the iris, if it occur, is seldom considerable, and, as a rule, easily reduced.

Mr. CHARLES H. B. SHEARS said that many of the most experienced operators, both in this country, on the Continent, and in America, still performed the combined operation, and for his own part he employed it as the routine treatment, reserving the simple method for cases with hard, brown lenses.

Mr. R. J. HAMILTON used a narrow-bladed knife and made the incision within the sclero-corneal margin. He considered that operators had the best results who could employ either the simple or the combined method.

Mr. RICHARD WILLIAMS said it did not matter a great deal which method of operating was adopted; but it was of great importance that the surgeon should be an expert in whatever method he might select. Personally, he performed the combined method of operating as he considered it the safer and the easier of the two.

Dr. W. MURRAY CAIRNS read a paper on the PRACTICE OF ASEPSIS IN OBSTETRICS, in which he made a strong plea for the more careful conduction of labour. At the outset he differentiated between aseptic obstetrics and *asepsis in obstetrics*. Precautions to be taken for the maintenance of the status asepticus before, during, and after labour, on the part of the surgeon, nurse and patient, were fully set forth. The advantages and disadvantages attendant upon the use of aseptic rubber gloves in obstetrical work were fully discussed, and the hope was expressed that a material more suitable for intra-uterine manipulation than rubber has hitherto proved might be discovered. A form of obstetric bag adapted to modern aseptic requirements was described. Asepsis in relation to (a) physiological, and (b) pathological labour was reviewed. In regard to the former, meddling manipulation was very strongly condemned; "hands off" was declared to be the keynote of aseptic labour. The use of lubricants was in general to be deprecated; if used at all, lubricants should, it was contended, be sterilised. The conditions under which the douche should and should not be used were laid down. Douching, ante- and post-partum, in strictly normal cases, was declared unnecessary. In all infective conditions, douching, both ante- and post-partum, was considered necessary, and it was recommended that it should always in such cases be antiseptic and administered by the surgeon. The advantage of asepsis over antiseptics was shown to be of considerable importance in the case of individuals who showed idiosyncrasy towards antiseptics. A strong warning was given lest the preliminary canons of cleanliness be overlooked—soap, water, nail-brush, and patience.

Dr. E. T. DAVIES, Dr. Llewellyn A. Morgan, Dr. Alexander Stokes, Dr. J. H. Finegan, Dr. T. B. Grimdale, Dr. J. H. Willett, and Dr. Nalini H. Blair took part in the discussion.

#### THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

At a meeting of the Society, held on October 21st, at 11 Chandos Street, W., Dr. FLETCHER BEACH in the Chair, four new members were elected and twenty-one were nominated for ballot at the next meeting.

Dr. C. O. HAWTHORNE showed a case of Hypertrophy of the Right Lower Limb. The patient was shown to the Society in 1902 ("Transactions," II., p. 114). The patches previously described as hæmorrhagic on the front of the leg ulcerated some twelve months ago, and have never healed. The question to be now decided was the advisability of amputation.

Mr. A. EDMUNDS advocated a prolonged trial of hospital treatment before recourse to amputation.

Dr. O. F. GRUNBAUM showed a Microcephalic Infant with Tropic Edema of the Feet, and a sister and brother with Congenital Hereditary Tropic Edema. The maternal grandmother of the two latter was also affected. The girl, æt. 7, showed swelling of both lower

limbs from the knee downwards, with harsh, thick skin of normal colour. The œdema was hard, but pitted on continued pressure. The size of the legs did not diminish on raising the feet, but could be temporarily decreased by applying a rubber bandage. The child had not complained of pain. The brother, æt. 5 months, showed a similar condition, and the hypertrophy of the skin was more easily demonstrated. In both cases the œdema was symmetrical. The cases were discussed by the Chairman, Mr. A. H. Tubby, Dr. F. Parkes Weber, Dr. J. Porter Parkinson, Mr. G. Pernet, and Dr. C. O. Hawthorne, and Dr. GRUNBAUM replied.

Dr. L. GUTHRIE showed (by permission of Dr. G. Ogilvie) a case of Cerebral Diplegic Athetosis in a boy, æt. 6, who had convulsions on the sixth day of an attack of measles last February. He was unconscious for seven weeks, speechless, paralysed on the right side, and lost sphincter control. At present he was regaining speech, did not seem mentally deficient, and had some sphincter control. There was no hemiplegia. He could not sit or stand, and had typical athetoid movements of the trunk and extremities.

Dr. GUTHRIE also showed a case of Polio-encephalitis (Cerebellar), occurring during measles last February. Intelligence was normal; speech, monotonous and scanning; slight tremor and ataxia of the upper limbs, and marked inco-ordination of the lower ones were present. The gait was typical of cerebellar disease. In commenting on the cases, Dr. Guthrie said that both were probably instances of polio-encephalitis during measles. In the boy the cortical and sub-cortical centre were chiefly involved, and in the girl mainly the cerebellum.

Dr. R. HUTCHISON showed a case of Habit Spasm in a boy, æt. 10. The spasm chiefly affected the muscles of the right side of the neck, had been present for two years, and had resisted all treatment.

Mr. Donald Armour, Dr. G. A. Sutherland, Dr. Porter Parkinson, Dr. C. H. Milburn (of Hull), and the Chairman discussed the case.

Dr. HUTCHISON also showed a case of Bromide Rash in a child, æt. 2. The spots were of the fleshy sort usually met with in young children.

Drs. Poynton and Parkes Weber made some remarks.

Mr. ARTHUR EDMUNDS showed a case of Infantile Paralysis with permanent involvement of the abdominal muscles. The attack had been very generalised and very severe. Now there was marked ballooning of the abdominal wall, in the area corresponding roughly with the distribution of the eighth and ninth dorsal nerves.

Dr. SUTHERLAND pointed out that without the history and the other evidence of infantile paralysis the case might have been mistaken for one of congenital absence of muscle in the abdominal wall, the cause of which was not well understood.

Mr. N. BISHOP HARMAN showed a case of Congenital Bilateral and Symmetrical Dislocation of the Crystalline Lenses. He suggested opening the anterior chamber and removing the capsule of the lens by seizing it with Couper's capsule-forceps.

Mr. SYDNEY STEPHENSON showed a case of Cerebral Degeneration with fundus changes in a boy, æt. 7.

Mr. P. LOCKHART MUMMERY showed a boy, æt. 8, with a dermoid cyst of the auricle in an unusual situation, rather too high up, in his opinion, to be due to a persistent portion of the intermaxillary cleft.

Dr. EDMUND CAUTLEY showed a child, æt. 3, with Congenital Heart Disease, Paralysis of the Left Superior Rectus, and an Abnormal Artery on the back of the Left Forearm. He thought the murmur due to a direct communication between the aorta and pulmonary artery, or to a patent ductus arteriosus.

Dr. CAUTLEY also showed a child, æt. 21 months, with a microcephalic head, imbecility, a moderate degree of spasticity, and irregular movements of the limbs and trunk. He regarded it as due to a combination of microcephaly and cerebral changes.

The Chairman and Dr. Parkinson commented on the case.

A photograph of Trichotillomania was shown by Mr. GEORGE PERNET, and one of extensive Herpes Zoster of the Left Arm by Dr. G. CARPENTER.

Mr. R. C. CLEMENT LUCAS read a paper "On an Ill-Developed Upper Lateral Incisor Tooth as a Fore-runner of Hare-lip or Cleft Palate."

Dr. E. GILFORD read a paper on "Two Cases of Congenital Diaphragmatic Hernia." In each case the child was *et.* 4 months, and had had no abdominal symptoms. One was moribund on admission to hospital, and was supposed to be suffering from sinus thrombosis. The other was admitted for bronchitis and paroxysmal dyspnoea. After death the third part of the duodenum, the whole of the small intestine, and the ascending colon had passed through an opening at the posterior part of the right half of the diaphragm. In neither case was there a sac. The cases were remarkable in their similarity to each other, and their dissimilarity from other recorded instances.

The meeting then adjourned.

### THE CHILDHOOD SOCIETY.

MEETING HELD OCTOBER 20TH, 1904.

SIR T. LAUDER BRUNTON, Bart., M.D., in the Chair.

#### A DISCUSSION ON

##### PHYSICAL DETERIORATION

was opened by Mr. E. W. BRABROOK, C.B., who said there was no evidence based on statistics to show deterioration. The best evidence could be gathered from large friendly societies, such as the Manchester Unity, with its million of members. True, sickness was increasing, but length of life also. Then the healthy and sensible were less inclined to marriage, so the recruiting of population came largely from the physically inferior.

Mrs. A. WATT SMYTH spoke strongly on the subject of milk depôts, urging that mischief done in infancy could never be undone, and advocating also the teaching of simple cooking to both boys and girls, and the selling of these meals at a minimum charge to the children as in Germany.

Dr. ROBT. HUTCHISON differed from Mrs. Watt Smyth concerning "irreparable mischief," as puny children sent to industrial schools often developed into sturdy ones. The milk depôts were becoming more necessary as the art and habit of natural feeding was, for reasons he could not then enter into, becoming less common. Food among the poor was not always scanty, but ill-chosen, and quantities of white bread, jam, and tea chosen instead of wholesome things such as porridge and milk. Even in High schools the interval, often 8 to 1.30, was too long, and rich children were often left to nurses. A type of man suited to congested city life was forming; the large frame was dying out and a small, wiry type coming in. Everything depended on food, a well-fed child could stand cold and want of clothes.

Dr. SHUTTLEWORTH thought deterioration was not more common, but more noticed. Society was becoming alive to defects, but still averse to providing funds for the necessary investigations and prevention.

Dr. WARNER was of opinion that the modern system of building high blocks of houses and excluding the sun from the children's only playground—the street—would eventually be a powerful factor in deterioration. Moreover, modern mothers should be taught to buy nourishing food and how to cook it, as education as well as light and air were essential to good growth. He would suggest schools being built out of the town and cheap cars be run to take the children to school.

The CHAIRMAN concluded that it was evident that much remained to be done in the way of steady investigation of facts and circulating, by demonstration and literature, the right rules which govern healthy living.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 30th, 1904.

### TAPPING THE BLADDER.

TAPPING the bladder consists in inserting, above the pubis, a trocar or needle of an aspirator into the bladder to evacuate the contents. Tapping through the perinæum or the rectum employed by the old surgeons has been completely abandoned to-day. This little operation, says M. Tuffier, is easily performed, and presents in itself no danger. It is possible to wound an important organ or the peritoneum, but by taking a little precaution the patient will run no risk. The bladder is in direct contact with the abdomen, and is situated immediately above the symphysis pubis, and when it contains about ten ounces of liquid the anterior peritoneal cul-de-sac is at a distance of from half to one inch from the symphysis, a distance sufficient to allow the bladder to be reached without injury to the neighbouring parts. However, it may happen that the peritoneum from adherence with the symphysis may be wounded; this accident, thanks to antiseptics and asepsis, is of little importance.

The trocar should be inserted in the median line, as it is here that the peritoneum is situated the highest up; but before operating, the surgeon must assure himself by palpation and percussion that the bladder is really distended. The instrument used can be a straight trocar, or the needle of a Dieulafoy or Potain aspirator. As in every operation, of no matter what kind, the teguments should be shaved and washed with a sublimate solution and alcohol.

The patient lies on his back, the legs stretched out, the operator seizes the needle firmly in his right hand, and, fixing with the index of the left hand the spot of insertion (half an inch above the edge of the pubis), he pushes it boldly in. The sensation of resistance conquered, the impression that the extremity of the needle is free, indicates that the bladder has been reached. If the bladder is greatly distended, it is preferable not to empty it completely, for fear of intravesical hæmorrhage; it is better to renew the operation a few hours afterwards if necessary.

The operation thus performed causes but very little suffering, and is inoffensive. It can be repeated as frequently as may be judged necessary, for it is less grave than catheterism imprudently executed. Before withdrawing the needle care should be taken to allow air to penetrate into the aspirator so as to avoid the possible infiltration of a few drops of urine into the tissue. Tapping the bladder is indicated in every case of acute urinary retention, where it is impossible to evacuate the reservoir by careful catheterism, as, for instance, in hypertrophy of the prostate; rupture of the urethra, fracture of the pelvis, and in certain forms of stricture. It sometimes occurs that in stricture it is impossible to pass the smallest catheter; if retention of urine exists, tapping should be immediately resorted to, and this operation is not only useful to the patient, but produces decongestion of the region of the urethra, permitting the easy passage of a bougie.

In acute retention from hypertrophy of the prostate, puncture of the bladder is very frequently indicated, and is absolutely necessary in the case of a patient who has been subjected to vain attempts at passing a catheter, and where a false direction may be feared. In old persons, where the urine is more or less infected, the hypogastric incision should be preferred to the puncture.

MIGRAINE IN CHILDREN.  
Antypyrene, xxx grains.  
Caffeine, x grains.  
Syrup, vi drachms.  
Water, ad. ii ounces.

A teaspoonful at the moment of the attack.

BERLIN, October 29th, 1904.

#### ACETOPYRINE.

THIS new antipyretic is said (*Deutsch. med. Zeitung*, '77, '04) to be an excellent agent for reducing temperature, also that it has no injurious effect on the heart. In toxic doses it is a respiratory poison; in medicinal doses respiration is rendered more shallow. Being excreted through the kidneys it increases diuresis; it reduces the size of the spleen. The pancreatic secretion is enormously increased, and this would lead one to conjecture that it would be useful in the pancreatic form of diabetes. The perspiratory stage comes on late and lasts only a short time. If other observers confirm the conclusions arrived at by Dr. Zwintz, to whom we are indebted for the exposition of the properties of acetopyrine, there will be hope that in it we shall find a useful addition to our armamentarium.

#### A SUBSTITUTE FOR IODOFORM—ALMATEIN.

Almatein is the name given by the makers to a new combination of hæmatoxylin with formaldehyde, and intended as a substitute for iodoform, for this useful but most objectionably-smelling drug is still in frequent use. A considerable number of cases are recorded by Bertini in which it was used in septic wounds, phlegmons and the like, and always with marked success. The powder is odourless, and that, no doubt, will commend it to all users of iodoform on other people, and it is also free from any toxic properties. The makers are Lepetit Dollfuss and Gausser.

#### THE ISOLATED UTERUS.

In the *Archiv. f. Gynäkol.*, 73, '04, is an article by E. N. Kurdinowsky describing the uterus after removal from the body. The isolated uterus, the writer says, can be seen on the second, and even on the third day, to make very energetic contractions, and to form a curve. In one case the uterus lived forty-nine hours forty minutes. The observer succeeded in reproducing the act of birth in all its individual parts, from the commencement to the end. The contractions caused the separation of the ovum. The cornu thrust its contents into the cavity of the uterus. Then energetic contraction of the ligamentum latum began; these forced the ovum into the vagina. The investigation showed that the birth act could be carried out in complete independence of the cerebro-spinal system. Cold and warmth acted equally energetically on the uterus, and, generally speaking, it was these oscillations that supplied the stimulus to contraction. The isolated uterus was but little susceptible to electric stimulation. These observations bring prominently forward the great probability of a local innervation.

Hydrastin did not act on the vessels of the isolated uterus. Ergot acted peripherally on the uterus quite independently of any contracting effect on its vessels. Narcotic poisons affected the uterus but very little. Adrenalin strengthened the contractile activity of the uterus more than any agent looked upon as specific. This, along with its great power of contracting vessels, ought to lead to further careful clinical study of the remarkable example of organo-therapeutics.]

At the Congress of Scientists and Physicians, Herr Magnus Hirschfeld showed some cases of

TRANSITION BETWEEN THE MALE AND FEMALE, one of which excited a good deal of interest. The case was that of a woman born in East Prussia in 1862, who really was a man. Believed to be a female at her birth, she was brought up as one; at sixteen her voice changed, and at twenty her beard grew, so that daily shaving was necessary. Her inclinations were decidedly male; she would rather be a soldier than anything. Towards men she had such a strong feeling of repulsion that she refused four offers of marriage which gentlemen who had been attracted by the stately and resolute "dame" made to her. On the other hand, she repeatedly fell in love with members of the female sex. When she was examined, it was found that the reproductive glands were male. Then it was proposed that she should dress and behave as a man, but she declined, as she could not face the sensation that such a complete *volte face* would be sure to cause among her acquaintances.

Dr. V. Kruedener relates a case of  
HERPES ZOSTER IN THE REGION OF THE FIRST LEFT  
BRANCH OF THE TRIGEMINUS.

The patient was a man, æt. 50, who, after a severe chill, had marked redness of the forehead, and the skin became covered with vesicles, which in part were black in colour owing to a partial gangrene of the parts. The following terminal branches were affected over the whole region supplied by them: the lachrymal, supra-orbital, frontal, supratrochlear, infratrochlear and the nasociliary. A few vesicles were on the bridge of the nose, and the redness extended about one centimetre over the middle line, this being in agreement with the observations of Zander on the subject, to the effect that the region supplied by the trigeminus of one side passes just over the middle line to the opposite side. The nature of the disease had been made a little more clear of late. If the Gasserian ganglion was to be viewed as a spinal ganglion, resemblance between the diseases of both would be shown. Treatment had to be directed to the nerve; aspermin and sweating brought about an improvement in a few days.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 30th, 1904.

#### THE DIAGNOSIS OF TUBERCULOSIS.

At the Breslau meeting, Kraemer criticised the latest opinions of Naegle on the frequent changes of tubercle in the lung. The chalky nature of tubercle, he affirmed, was not yet proved, neither could we be assured that it was infectious, nor on the increase if statistics are to be believed.

In the diagnosis of tuberculosis in the lung, Freymuth recommended the administration of Koch's old tuberculin in the form of pill covered with keratin. This acted as promptly in exciting the febrile reaction as when injected subcutaneously. Different intensities of fever were measures of the progress of the disease, and as the bacilli did not appear in the sputa at the commencement of the disease, a few pills of tuberculin were of great value in the diagnosis of obscure cases. One point he wished to impress on his hearers was that when given internally the fever was not as intense in the very early stages as in subcutaneous administration, which may be proved by giving a stomachic dose and subsequently a very small subcutaneous injection, the system seeming more sensitive after an internal dose.

Nourney said he was a great believer in tuberculin treatment, after several years' experience with small doses not exceeding 0.0001 gramme. This was equally efficacious in the cure of lupus.

Holdheim recorded the history of two cases under treatment with tuberculin for two years with ultimate cure. Other fifteen cases were greatly improved by its application.

Pauli regretted the general disuse of tuberculin in the treatment and early diagnosis of tubercle in the lung. Tuberculin was of no value as a diagnostic in patients under twenty-two years of age.

Schneider would not discuss the propriety of the use or disuse of tuberculin, but urged enthusiasts to be guided by the pulse frequency in their prognosis of cases. If the pulse ranges above 100 per minute the case is a very grave one, and may become aggravated by many forms of treatment.

#### HYPERÆMIC TREATMENT OF PHTHISIS.

Wassermann gave a description of his theory of the passive hyperæmic treatment in phthisis. He accepts the dictum that tuberculosis is the result of anæmia of the lung, and contends that gymnastics are the rational method of dealing with phthisis. With the same object in view he causes a narrow opening for inspiration, leaving the mouth free and open for exploration. With an instrument of this kind the breathing is laboured, while the force produced causes passive hyperæmia in the lung, which ultimately produces a healthy condition of the organ. In all his experiments with this treatment he has never met with hæmoptosis.

#### BACTERIAL ACTION OF SERUM IN TYPHOID.

Stern gave many examples of bacterial action in blood serums, particularly the typhoid bacilli, when treated in the test tube. He applied fresh blood of a typhoid case to a bouillon culture to prove that the blood serum of typhus had no more action than the blood serum of a healthy man. The interest of this experiment lay in the newly drawn blood, which he attempted to prove was less active than the bacilli after cultivation. He thought this was the cause of many of our failures in the production of immunity by different sera, and was of the opinion that this destroyed the theory of an intermediary body or immune principle that it was necessary for the protection of typhoid.

#### RECURRENT TYPHOID.

Hodlemoser gave his experience of an epidemic of typhoid recurrens which raged for a long time in Herzegovina. He tried on several occasions to cultivate a serum, in the hope of producing immunity, but found it difficult owing to the recurrent spirillum disappearing during the interval, and at the same time affirmed that the Obermeier spirillum was very difficult to cultivate.

## The Operating Theatres.

### KING'S COLLEGE HOSPITAL.

COMBINED SUPRAPUBIC LITHOTOMY AND PROSTATECTOMY.—Mr. CARLESS operated on a man, æt. 66, who had been sent into the hospital complaining of pain before, during and after micturition, and associated irritability of the rectum, the bowel emptying itself every time micturition was attempted. These symptoms had gradually increased during the last four months, and the pain now continued for about twenty minutes in all. It was located deeply in the perinæum, and did not extend to the tip of the penis. There had never been hæmaturia, but the urine contained some

mucopus, together with phosphatic and oxalate crystals. A certain amount of mucus was evacuated by the bowel. On palpation nothing abnormal could be felt through the abdomen, but on rectal examination the prostate was found to be considerably enlarged. On the introduction of a sound, the presence of one or more vesical calculi was determined. The patient was anæsthetised, his pelvis raised and the bladder washed out with boric acid lotion, about half a pint being left in. The usual suprapubic incision was then made, and the bladder exposed. A silk sling was passed through the vesical wall on either side of the middle line, and the viscus incised from above downwards. The mucous membrane was secured on either side with Spencer Wells' forceps and held well up; it was found to be thick and congested. On the introduction of the finger the prostate was found to be large and projecting into the cavity, and in the pouch behind it a whole colony of stones was discovered; they were removed by forceps and fingers, and were found to be nineteen in number. The mucous membrane at the back of the prostate was next incised and the enlarged prostate enucleated without difficulty, coming away in two portions, the urethra apparently being left behind; this was facilitated by pressing the prostate upwards with the fingers of the left hand in the rectum. A sterilised india-rubber glove had been worn thus far on the left hand; it was then removed, so that the left hand, after purification, could be used in the remainder of the operation. The incision in the bladder was closed around a tube passed into it by catgut stitches which missed the mucous membrane. The upper part of the space between the recti muscles was closed by similar sutures, and the upper part of the skin round approximated. The cavity then left was packed with gauze, and an ordinary dressing applied. Mr. Carless pointed out that the absence of the typical symptoms of stone in this case was due to the calculi being located behind the prostate, so that they were not brought in contact with the internal meatus during micturition. They were of a light brown colour and most of them quite smooth, though many had blunt projections on one or other side. One of them was long and narrow-shaped, somewhat like a banana. They were probably composed of uric acid. The prostatic enlargement, he said, was of the ordinary senile character, and the masses removed showed well that they consisted of multiple rounded bodies, probably adenomata united together to form one mass, which, however, was easily broken into two along the anterior and posterior commissures. Mr. Carless' firm opinion was that most cases of prostatectomy consisted of an intra-glandular enucleation of adenomatous masses. In this particular instance, he remarked, the growth was apparently peeled off the urethra, which could be felt in the cavity left behind; it was probably a matter of very little importance whether the urethra was retained or not during the process of cicatrisation that followed. The mucous membrane of the bladder was approximated to that of the membranous urethra, and the cavity was always sufficiently large to obviate any likelihood of the development of stricture.

### ROYAL FREE HOSPITAL.

ENUCLEATION OF THE EYE FOR INJURY.—DISCOVERY OF A NEEDLE .038 M.M. LONG EMBEDDED AND HIDDEN IN THE EYE AND ORBIT.—The case, which had been

admitted under the care of Mr. WORK DODD, was that of a man, æt. 37, who gave the following history: In the morning the patient had been shaking out a new shirt, which was very stiff with starch, when a china button on the sleeve cuff hit him full in the left eye. He had sudden and acute pain, and said it felt as if the eye had been knocked out. On looking at it in the glass he saw a spot of blood on the inner side of the eyeball. The man walked to the hospital, and stated that he did not lose his sight till he got there. Nothing abnormal could be discovered on admission concerning the past history or in the general condition of the patient. Locally the left eye was hyperæmic and very painful, and nearly all sight was lost in it, barely perception of light being left. On examination for an external wound from the blow, there was a doubtful spot, which might have been a solution of continuity, on the inner side just above and .002 m.m. from the edge of the cornea opposite the insertion of the internal rectus muscle. The anterior chamber was filled with blood. The tension was extremely low, -2. For the first two days the patient improved slightly under treatment (mercurial purge, atropine, and boracic lotion), but on the third day there was a good deal of chemosis and the cornea looked very hazy. On the fifth day this condition was unchanged, and, in addition, the eyeball was proptosed and there was considerable orbital cellulitis and what appeared to be hypopyon. Mr. Dodd decided on enucleation of the eye, and suggested before operation the presence of a foreign body. The operation was performed in the usual manner. The optic nerve was severed as far away from the eye as possible. On the eyeball being extracted from the orbit, the broken end of a needle about .038 m.m. (1½ in.) long was seen projecting from the inner part of the eyeball, which last was itself full of pus. The direction of the needle was from the apex of the orbit outwards and forwards to a point outside the cornea on the anterior surface of the eyeball, but there was no hole in this situation through which the needle could have entered. There was nothing in the interior of the eyeball to indicate the track of the needle; there was, however, a small hole through which pus exuded about .002 m.m. to the inner side of the corneal margin. A careful search was made in the orbit and in the eyeball for the point of the needle, but it was not found. Mr. Work Dodd said that the most peculiar thing about the case was that the history of injury from the china button and sleeve was remarkably clear, and was given and repeated without any hesitation or doubt by the man, who was intelligent in all his assertions. Therefore, it must be accepted as a fact that the accident did occur. On the other hand, there was entire absence of any history pointing to a needle being concerned in the accident, and he thought this showed how little the surgeon can rely upon the history given by a patient. (It may be mentioned, however, that, after the operation, the patient, on being shown the needle, remembered that, some time previously, he had been sewing a button-hole in the shirt and had left a needle hanging on a short end of thread.) Mr. Dodd pointed out that the man had been treated for two or three days for contusion and bleeding into the globe, but as the eye did not clear up and became, on the contrary, inflamed, and pus having formed, he commenced to have the suspicion of the presence of a foreign body. The presence of the needle, however, in the eye and orbit, he

said, came as a great surprise, and its method of arrival in these localities was, he considered, very difficult to ascertain. It was possible for the needle to have stuck itself into the eye as a result of shaking the shirt violently, and then to have been hammered home through the ball by the cuff and china button, the hand being probably at once pressed against the eye, the whole occurring as one action. A pointless needle .038 m.m. long would have to travel with enormous rapidity to pierce through the sclera in front and behind, besides passing through the interior of the globe and finishing up towards the orbital apex. The ophthalmoscope, he remarked, could be of no assistance in this case, as the eye was full of blood; and the fact that the tension of the eye was *below* normal, a condition which is not uncommon after contusion of the globe, would not necessarily point to a rupture or to a perforation. These two conditions, and also the presence of a foreign body, lower the tension of the globe. Mr. Dodd said he was glad that he had suggested the presence of a foreign body in the eye. He had only done so because experience had taught him to be always on his guard in this respect. He pointed out also that, as there had been no indication of any such thing, there had been no resort to X-rays.

Ten days after the operation the patient left the hospital perfectly well.

### THE “BORSTAL” SYSTEM.

WHILE so much talk is being expended—and rightly expended—on the ways of the “degenerate” and the methods of dealing with him, a glance at the other side of the picture may be taken with advantage. Ultra-humanitarianism may bring derision on the heads of all who are striving to establish a more humane code of ethics, just as the reproach of barbarism is frequently brought

against those who err on the side of severity, but there is no denying the fact that the humanitarians are on the up-grade. How far the principles of altruism are compatible with, that is to say advantageous to, the existence of a civilised state is an interesting problem that remains to be worked out. The evidence of the last century is all in favour of the social advance of that state in which regard for others is substituted for brutal indifference. The reason may not always be apparent, but the fact remains, and to medicine must be assigned the first place as a civilising and humanising force. The work and mission of the medical profession brings and keeps its members in constant contact with every class of society down to the lowest, and this at the time when the softer feelings are most apparent; namely, in the time of sickness. Consequently one finds the influence of medicine generally on the side of mercy—to the great advantage of society generally. In no domain more than in that of crime and criminology is this apparent, and in no field has medicine greater triumphs to show. The desire for revenge and for punishment is one of the most elemental of human forces, and the sheer stupidity of giving it unrestricted play in dealing with delinquents has been demonstrated in the criminal annals of every country that possesses annals. Humanity in the treatment of offenders has shown itself to be not only the right but the wise course, and the old savage punishments are, happily, passing out of fashion. The report of the Directors of Convict Prisons, just issued, gives a full account of the working of the so-called "juvenile-adult" system that has been inaugurated at Borstal, and we may say at once that the verdict of the Directors is wholly favourable. This system was inaugurated as an experiment to exploit the plan of treating young criminals with a view to curing, instead of merely punishing, them. From the London prisons were collected cases of youths sentenced to terms of imprisonment of six months and upwards, and these lads were put to learn useful trades, such as carpentering and brick-laying, under beneficent supervision, instead of performing the old routine of purposeless prison tasks. The conduct of the prisoners under the new set of circumstances completely changed; they showed great anxiety to improve, and they were granted extra privileges, became great readers and good chess-players. Nor was this improvement only temporary. So far a hundred and twenty-two "juvenile-adults" have been discharged, and of these, fifty-four are now known to be in employment and leading useful lives, whilst thirty have been lost sight of. Of the remainder, only twenty-four have been re-convicted, and fourteen are still unplaced. Considering that more than a hundred of these cases were hardened young criminals, fifty-one of them having been convicted more than once, and twelve more than three times; that they were discharged in London where they had either no homes or

thoroughly bad homes, and where every temptation existed to glide back to their old haunts; and that the task of supervision after discharge is extremely difficult, one is not surprised that the Directors write enthusiastically about the success of the scheme. They are now planning to extend it so as to reach not only London, but the whole of England and Wales, and to establish it on a permanent basis. Two elements are necessary for a complete cure—time in the prison and supervision afterwards. The first depends on the sentences passed, but it must be borne in mind that the lengthening of sentences is opposed to the whole trend of modern enlightened philanthropic feeling. In order to secure the second condition the Directors suggest the formation of a "Borstal Association," a permanent voluntary agency, to watch over and interest people in the youths when they finally leave prison. We are glad to note that this Association is already on foot, the Home Secretary having consented to act as president, and the Archbishop of Canterbury, the Bishop of London, the Lord Chief Justice, Mr. Asquith and others, as patrons. Now, at last, it seems that rational methods are to have a fair chance in the treatment of criminals, and that the old, blundering brutality—for it has been nothing less—is to become as extinct as it now is in our asylums for the insane. At least we hope so, for it is too early to speak definitely yet. The introduction of lectures on nursing, sanitation, and such-like subjects into female convict prisons that has just been started by some philanthropic ladies—lectures that are greatly appreciated by the prisoners—looks like confirmatory evidence, and we trust the day may not be far distant when criminal therapeutics will become a distinct branch of psychiatry. At all events, we venture to congratulate the Directors of Convict Prisons on the success of the Borstal experiment, and to wish the Borstal Association ready and substantial support in its enlightened labours.

#### TREATMENT OF TRIGEMINAL NEURALGIA.

ALTHOUGH never in itself dangerous to life, trigeminal neuralgia frequently becomes one of the most serious and intractable of diseases. Suffering from incessant and severe pain, to which nothing gives any real relief, it is no wonder that the patient becomes sometimes a moral and physical wreck, broken down by want of sleep and rest, a victim to drug-habits, ultimately degenerating, perhaps, into insanity, or developing a fatal tendency to suicide. In such severe neuralgias medical treatment is, as a rule, unavailing, but, of course, it should be given a thorough trial before surgical methods are thought of. The latter are, however, upon their trial at present, and there are many cases unfortunately in which they appear necessary. Historically, the earliest operation practised for neuralgia was a neurotomy or neurectomy of one or more branches of the

trigeminal nerve. Very often this is found to give considerable relief, though in some cases it entirely fails, and in all the neuralgia tends to recur. It is, however, a quite safe operation, and should always be considered before graver methods are adopted. The graver methods which are in vogue at present agree in the common feature of intracranial neurectomy. Some surgeons think it sufficient to remove the sensory root of the fifth nerve, while others advise the partial or complete excision of the Gasserian ganglion. There is but little difference in the final result whichever practice is adopted, though undoubtedly the removal of the ganglion presents some difficulties of *technique* and special dangers absent in the more simple neurectomy. At the same time, it is believed that there is somewhat less likelihood of recurrence when the ganglion is removed. It need hardly be pointed out that the operation is one of the most serious that can be undertaken, and that it is never justified unless the disease has shown itself intractable to less radical methods. On the other hand, it is inadvisable to postpone the operation until the patient has been reduced by pain and loss of rest to such a condition of weakness as to render any operation a danger. In the performance of the operation itself, the chief risk is from hæmorrhage, though many deaths are reported from shock, from sepsis, and from injury of the brain. The mortality during recent years has probably been 20 per cent., a high figure when it is remembered that the disease itself is not fatal. The difficulty and danger of the operation will probably act as a bar to its adoption by other than daring surgeons, and there is at the present day a tendency to look back to extracranial proceedings with the hope that some treatment may be found which, if not as complete in its final result as intracranial neurectomy, will yet offer hope of prolonged relief. A simple procedure, and one that has already given good results, is that recommended by Sir William Bennett and by Mr. John B. Murphy, of Chicago, namely, the injection into the nerve-trunks of weak solutions of osmic acid. The nerves are exposed and a few drops of a 2 per cent. solution of the acid are injected at several points. Murphy advises that all the main branches of the fifth nerve should be treated in this way, as it is well known that once the neuralgia has affected the nerve, all the branches are likely ultimately to suffer. Murphy's cases are too recent to permit one to say that osmic acid gives permanent cure, but in many of his cases and also of Bennett's there has been a complete cessation of pain for periods of from one to four years. As the operation is entirely devoid of risk it is likely that it will become fashionable in the near future, even if it should be found that the effect is not permanent. It is better that a simple operation should be repeated when necessary than that the life of a patient should be endangered by a superfluous intracranial operation.

## Notes on Current Topics.

### Soap Before School.

THE Education Committee of the London County Council have begun well in appointing a nurse to examine children with regard to cleanliness before entering school in the mornings, and to refer those who appear unsuitable to a doctor, who has authority to refuse admission. This is as it should be. Underfeeding may or may not be due to parental neglect, under-washing always is. It is monstrous to expect clean and careful parents to send their children to sit next to filthy urchins with verminous heads, and it is mere waste of time to insist on other hygienic requirements when the primary step in all health questions, namely, cleanliness, remains untouched. Unfortunately the powers of the education authority seem limited with regard to this question, for at Worship Street Police Court the other day, a batch of summonses against parents for non-attendance—the non-attendance being due to the children having been sent back for dirtiness—were dismissed. An obvious loop-hole exists if this is the state of the law, for a careless parent may purposely neglect to keep his children clean, and then plead that they were excluded from school when he did send them. When the summons is taken out, the children can be cleaned for the purpose of appearing in court. In the cases reported there seems to have been more misunderstanding, for the parents are said to have cleaned the children and taken them back to school, and been again refused admission. If, however, difficulties are likely to arise it would certainly be wise to have full powers conferred on the officers of education authorities to deal with dirty children, or rather their parents, for the County Council Education Committee seem determined to deal with what has been a reproach in days past, and it will be a great pity if their efforts are thwarted or hampered by insufficient powers. If the teaching of the simple laws of hygiene is to be introduced into elementary schools, as we all hope, the first lesson had better be an object-one of the detergent virtues of soap and water, and in so far as example is better than precept will the pupils be impressed with the value of the instruction afforded. Cleanliness is subordinate to godliness only in the sphere of morals; it is subordinate to nothing in the sphere of hygiene.

### Imagination as a Cause of Death.

THERE are two or three stories going the round of the newspapers at present which illustrate the powerful effect the imagination can exercise over the phenomena of life. In one case a girl, suffering from despondency of spirits, is said to have swallowed some harmless fluid in mistake for carbolic acid. She immediately declared that she had poisoned herself, and soon died, though we are left without any information as to the nature of the symptoms, or of the lesions discovered

*post-mortem*. An equally peculiar case is reported from Hull. A young woman asked at a chemist's shop for some laudanum, but the attendant, noticing that she was in an excited condition, supplied her with port wine. Shortly afterwards she was discovered apparently suffering from opium poisoning, and the usual anti-opium treatment was successful. Though we have no authority beyond newspaper currency for either of these stories, there is nothing in them inherently impossible. Apart from the extraordinary mimicry of which hysterical subjects are capable, there are several well-authenticated instances in which death has been the result of quite imaginary causes, or rather of the fright resulting therefrom. Perhaps the best known of these is the case of the jester of a Scottish Court, who, in punishment for some offence being threatened with beheading by a party of courtiers, was then made to kneel before an improvised block, and struck on the neck with a wet towel. To the astonishment of the party, he did not move, and was actually found to be dead.

#### Identification by Finger Prints.

THE inquiry that has just been made into the case of Mr. Beck has not unnaturally excited wide-spread interest, and every respectable citizen would be glad to know that the recurrence of such a heinous blunder will be as impossible in the future as it has always been thought to have been up to the present. Every man has at least one "double," and most people would gladly sacrifice any reflected glory that might shine on them through the achievements of their doubles for the comfortable assurance that the latter's crimes could not possibly be visited on their heads. Fortunately, that practical branch of anthropology which deals with identification has made great strides, and the system now in use by the police is a great advance on the haphazard methods in vogue before 1894. In that year a committee was appointed by the Home Office to inquire into the matter, and their recommendations were accepted. At present each prisoner has an identification card bearing on one side accurate measurements of the essential bodily characteristics, together with a photograph and particulars of complexion, hair, eyes, scars, and other distinctive marks, whilst on the reverse are places for the finger prints. A Scotland Yard inspector mentioned in evidence in a recent case that the Department have no less than 70,000 impressions of finger-marks, and that no two of these are exactly alike. As showing the difficulty of obtaining official recognition for a new art—for the reading of finger-prints is little less—it may be interesting to recall that Sir William Herschel introduced it into Bengal in 1877, and reported favourably on its general applicability. He probably derived his inspiration from finding the practice of signing documents by thumb-marks prevalent in certain parts of India, but in spite of his advocacy the plan was discarded after his

departure. The credit for having reduced the study of finger-prints to an exact science belongs, of course, to Mr. Francis Galton, and it was he who was able by his two great works, "Finger-Prints" and "The Decipherment of Blurred Finger-Prints," to convince the world that the subject had practical bearings beyond those of a hobby for anthropologists. Under the auspices of M. Bertillon the method was many years ago adopted in France. The registration of the papillary ridges of the fingers in indelible form constitutes the most exact single record of identity at present known, and is, moreover, obtained so easily that the future may hold important developments for the art in commercial and general life, beyond even what it has already done for the detection of criminals.

#### Florence Nightingale.

THE recent publication of a biography of Florence Nightingale brings to memory the fact that it is just fifty years ago that the patron saint of the nursing profession and her heroic followers sailed in the time of dire need to succour their wounded and suffering countrymen. We have said the patron saint, for if ever a woman deserves secular canonisation that woman was Florence Nightingale—the founder of modern nursing with its inestimable blessings to the sick, and breaker of red-tape in the Army Hospital Service of her time. The remarkable fact about Florence Nightingale's character was that with a fund of sympathy and skill in nursing individual cases of sickness, she combined truly remarkable powers of organisation, and while it is by the former that her memory will live and be cherished, to her administrative skill and boldness must be assigned the real power she exerted among the authorities. Her influence on the soldiers is illustrated by a touching story told by Sidney Herbert. One of the wounded, speaking of the experiences of his ward, said that Miss Nightingale always found time for a smile and a bright word for some of the sufferers, though their numbers were too great to allow of her recognising and speaking to all; "but," he added, "we could kiss her shadow as it fell, and lay our heads on the pillow again content." Strong woman as she was, the Crimean war broke Miss Nightingale's constitution, and she has led a retired and mostly an invalid life since she returned to England, under the *alias* of "Miss Smith," which she assumed to avoid the ovation prepared for her. Even in her seclusion she has worked hard and steadily for the raising of status and the training of nurses, and from them she has never demanded a lower standard than she lived up to herself. The age of eighty-four still finds her alive to the movements that are taking place in the service she loves, but her active work is over. One might have thought that the fiftieth anniversary of her departure for the Crimea would have been seized upon by nurses as an opportunity for a celebration, for it would be a real and serious loss if the example of Florence

Nightingale were to fade from the memories of her modern successors.

#### Municipal Dentistry.

WE have often urged in these columns that some method of dealing with children's teeth is urgently needed, and that it would be a great advantage if such inspection and treatment could be made available for the working-classes generally. The amount of ill-health and digestive trouble attributable to unsound teeth is incalculable, and returns from every source show the evil to be increasing to an extent that can almost be termed alarming. The difficulties that stand in the way are each of interest in the question, and the all-important question, of expense; certain it is that the latter will never be solved till the former changes considerably. To those who are disposed to make the matter a practical one, the experiences of Germany should be of help. Some of the large towns in that country have both the power and will to appoint municipal dentists, and these officers are already at work. In Strasburg last year 2,666 children were subjected to dental inspection, with the result that no fewer than 2,912 teeth were found too much decayed to be saved, and were therefore extracted, whilst 699 were stopped. The plan that is followed is for each teacher himself to take his class to the dentist, who examines the children one after another, noting on a card the state of the teeth as he finds them. When defects are found the patients are ordered to come up on a Saturday, and the extractions and fillings are then performed. Not only is the importance of sound teeth being recognised in Germany, but Russia—one of the most backward of the great civilised powers in questions of public health—is also taking the matter up, and nine municipal dental institutes for the supervision of teeth have been set up in St. Petersburg alone. These facts, surely, may serve to strengthen the hands of those who would like to see similar advantages conferred on our elementary school children.

#### Intravenous Injection of Salicylates.

IN the administration of many drugs it is known that more excellent results can be obtained when intravenous or subcutaneous injection is practised than when the drug is given by the mouth. Certain drugs, too, lose some of their power when absorbed through the stomach, so that, if a full effect is to be gained, some other method of administration must be practised. This seems to be the case with the salicyl compounds, and for some time various physicians have been in the habit of injecting salicylate of sodium hypodermically with better result than is obtained by the usual method of administration. More recently intravenous injection has been recommended, and has been practised with success by Mendel and others. He usually gives four-grain doses, repeating them at intervals of from twelve hours to three days. In no case were

any ill-effects noticed. In the *technique* of injection the same precautions are necessary as in intravenous injection for any other purpose. The vein should be fully dilated before inserting the needle, and care should be taken that the needle really pierces the vein. In repeating the process, a different vein should be selected. The method of treatment seems to have a wide application, not only in acute rheumatism, for rapid relief has been given in such conditions as lumbago, and the flying pains to which rheumatic patients are so subject in damp weather.

#### Organisms in Sore Throat.

IT has been the experience of most clinical bacteriologists who have to do with the study of cultures from the throat to meet from time to time with cases which present every clinical appearance of diphtheria, but where nevertheless the diphtheria bacillus is absent. Different observers have noted various organisms as being found repeatedly in such cases, but few of them have established a causal relation with the same rigour as has recently been done by Dr. Stone in the States with regard to a diplococcus discovered by him. (a) The diplococcus in question was separated in about a hundred cases, most of which belonged to a quite definite type. There was an acute inflammation of the throat, accompanied by a severe toxæmia, which usually subsided on the second day. In about half the cases there was a membrane present, white in colour, tenacious, and indistinguishable in appearance from the membrane of diphtheria. There was also swelling of the tonsils and œdema of the soft palate and uvula. In addition to cases of this description Stone found the diplococcus in several cases of follicular tonsillitis, and in a few cases of scarlet fever, but in no case was it found in a healthy throat, although over two hundred such were examined. The appearance, staining, and cultural reactions of the organism are sufficiently distinctive, and a positive result is got by the inoculation of animals. In all the ordinary laboratory animals the organism proved to be pathogenic, a diphtheritic exudate appearing on the serous membranes, from which the organism was recovered in pure culture. In no case, however, did an exudate appear on the mucous membranes of the laboratory animals.

#### Meat Extracts in Medicine.

THE exact place of meat extracts in the feeding of invalids is hardly yet grasped by practical physicians. That view is borne out by the sweeping statements that so often run the round of the press, both lay and medical, to the effect that the average meat extract contains no sustenance or nutriment, and that it is merely a stimulant. The average journalist seems to think that when he has uttered those sapient remarks there is nothing more to be said on the matter. Reflect for a moment what stimulation means as a weapon in the hands of the physician faced at the bedside with the problem of how to stay the havoc wrought

(a) *Medical Record*, August 18th, 1904.

by a failing circulation and a thwarted nutrition. As a stimulant alcohol is often his sheet anchor. In many a case we have no hesitation in saying that a good meat extract is a thousand times better than whisky or champagne, inasmuch as its stimulation is not followed by the reaction and depression, bodily and mental, induced by alcohol. Many a time have we seen a patient tided over the rocks into the haven of recovery by the use of the beef-tea and meat extracts that scientists of the study-table order love to deride. Medical men and nurses will do well to think for themselves, and be guided by their own experience rather than by the long-drawn theories of others. Let them choose good extracts made by good firms, and if they want more nutriment therewith let them add milk or cream or whites of eggs.

#### "Sundown" Journalism.

THERE are many men of nervous temperament who never seem fully alive to their work until the end of the day. The dullard of the breakfast-table becomes transformed into the after-dinner wit, while the maiden throws off the listless languor of morning, to emerge later as the beautiful star of evening. But while the fire of nervous energy is at its brightest the ashes of wear and tear are falling at their fastest. It is hardly to be expected that real hard work which shall stand the test of time can be performed late at night, when both body and mind have toiled laboriously throughout a long day. And yet it is well known, especially in the journalistic world, that a considerable proportion of "copy" is written by the light of midnight oil. Dr. T. D. Crothers, in a paper read before the American Medical Editors' Association, has drawn attention to the unequal literary work sent in to medical editors, even by the same authors, which he attributes to the fact that much of it is done after sundown. The literary life is one of stress and strain, and the more so if it be combined with other occupations. In this is probably to be sought the explanation of the "literary patchwork" which is sometimes painfully obvious, even in standard text-books by eminent clinical teachers. The recognition by authors themselves of their inability to do really good work when tired out has, unhappily, led them to the use of artificial brain stimulants. Dr. Crothers considers that many of the articles which appear in the medical journals of his own country convey a distinct impression that they have been written under the influence of extreme fatigue or of drugs, which may account for the hopeless note of failure recognisable in not a few of the ephemeral periodicals of modern times, lay as well as medical.

#### Medical Men in Lay Newspapers.

THE letters of medical men to the daily newspapers on professional subjects are multiplying beyond all bounds. Now, either this is or is not an offence against medical ethics. The London College of Physicians denounce all advertising, direct or indirect, but we find its Censors,

Members and Fellows, nay, even its ex-Presidents, communicating this, that, or the other information under signature to the *Times* and other public prints on cottage hospitals, consumption cures, cancer, X-ray methods, and what-not. The Colleges are no whit greater offenders than many of the members of the honorary staffs of leading Metropolitan and provincial hospitals. What can be said, then, if the rank and file of the profession follow suit, and flood the correspondence columns of the daily press with their views upon any or every matter within the range of medical literature? Where the offenders are to be found in every class it is, perhaps, invidious to mention one. Yet we think the letter of Dr. J. Stenson Hooker to the *Daily News* of October 24th may be briefly alluded to as an example of the superfluous and misplaced energy in question. He informs readers of that journal that the "violet-leaf cure" of cancer has been tried at the Brompton Cancer Hospital, and found wanting. He then proceeds to suggest that red clover top is worthy of trial in the disease mentioned. Surely Dr. Hooker should have made this suggestion to medical men in the columns of the medical journals, and not to the general public. However, many hospital surgeons and physicians have led the way in the same undesirable direction.

#### A Surgeon's Account of the Russian Outrage.

THE secretary of the Royal National Mission to Deep Sea Fishermen has received the following "human" document from the surgeon on board the hospital ship *Joseph and Sarah Miles*, which has the three seriously wounded men on board from the *Crane* :—

"Hospital Mission Ship, *Joseph and Sarah Miles*,  
"Great Northern Fleet, October 24th, 1904.

"Dear Mr. Wood—Before this reaches you, perhaps you are acquainted with the sad news of a dastardly raid on our fishing fleets last Friday night by some foreign battleships. The incident came upon us so sudden and unawares, that we cannot yet realise what it could be. Happily our fleet had no casualty on that fateful night, but the Gamecock fleet, which was working close to us, fared very badly. One of their trawlers sank in a few minutes after being hit by four shells, killing two of the crew and badly wounding the rest. Four of their other trawlers were also hit. The shipwrecked crew were luckily rescued from a watery grave by the crew of another trawler, whose first thought, of course, was to look out for their own mission ship, but before they could find the *Alpha*, they sighted our ship, so they steamed up to us and shouted out for urgent help as some of the wounded men were bleeding to death. The sad news in itself was enough to stagger us. We hauled up our gear at once and launched out our boat, and soon I was aboard the trawler with two of our crew, I have never witnessed such a gory sight as I did on board the trawler. Two men lay on deck with their heads nearly blown to pieces. In the cabin the scene was more heartrending still, when I saw six men stretched about anyhow, bleeding and groaning, with the agony of their wounds. Under the circumstances, I had them all removed on board our ship. With all these wounded men on board, our floating hospital looked like a veritable battlefield. Indeed, it presented a most pathetic sight. It kept me busy with knife and needle the whole of that day, and it was not until late in the night that I had the satisfaction.

of seeing them all safe and snug in their cots, as far as circumstances allowed. But of the six patients three have been allowed to return to their homes, as they were progressing satisfactorily. Of the remaining three, one is quite out of danger, but the other two being very serious cases, I am still anxious about them, and, circumstances permitting, I shall have to send them on to London if they do not progress favourably.—Believe me to be yours sincerely, H. ANKLESARIA."

#### Dr. Ettles as "Medical Referee."

A FORTNIGHT ago, writing on the alleged new treatment (it is really old as the hills) of errors of refraction by massage, we alluded to a public trial of the matter proposed between Dr. Stephen Smith, its "inventor," and a London optician, Mr. Aitchison. On the authority of a daily newspaper, we stated that Dr. Ettles, of the Minorities, had been appointed as referee by Dr. Stephen Smith. This notice was followed a few days later by a letter from a legal gentleman representing Dr. Ettles, disclaiming, on the part of his client, all acquaintance with Dr. Stephen Smith or his methods, and sympathy with anti-vivisection. On receiving this letter we at once proceeded to publish that correction, and to make amends as far as possible for the misapprehension which seemingly we had been led into on the strength of published statements in a London newspaper. It now appears, from a letter in the *St. James's Gazette* of October 28th last, signed by Mr. James Aitchison, that it was he who appointed the referee. "Dr. Ettles, the ophthalmic surgeon," he writes, "whom I appointed to act for me, states—'Mr. Smith will only submit to a test on his own terms, and as those are of such a character as to make the thing an absolute farce, it is out of the question to give way any further.'" Dr. Ettles, it appears, is acting as referee for an optician, not, as we were led to believe, for a qualified medical man. Further comment upon this incident is needless in the columns of a medical journal.

#### Poisoning by Boot-Blackening.

A FATAL case of poisoning, apparently unique in the annals of toxicology, is reported in an American contemporary. (a) A young man, having spent some hours at a dancing party, suddenly fainted in a public café and passed into a state of stupor. Although treated with injections of strychnine, his condition became worse and he died four hours later from paralysis of the circulatory apparatus, no clue being apparent as to the cause of the illness. *Post-mortem*, also, the findings were negative, except that there was an acute desquamative nephritis, and fatty degeneration of the cells, both of the liver and kidney. The tentative diagnosis of poisoning was made, but the cause was quite unknown. Some days later, however, a bottle of shoe-blackening was found in the victim's room, and it was discovered that on the evening of his death he had soaked in this blackening the tan uppers of a pair of canvas boots, and that the colouring had penetrated his stockings, staining

his feet and ankles. Chemical investigation of the substance revealed that the solvent in the blackening was nitrobenzol, an extremely poisonous liquid, much used in the manufacture of cheap perfumes and soaps. Several cases of poisoning by nitrobenzol were already on record. In some, serious results followed a mere breath or two of the vapour, in others on a small dose of the liquid, but we think this is the first where the result is due to absorption through the skin. The occurrence draws attention to the danger of using such a highly toxic substance in the preparation of so many promiscuous wares as soaps, shoe-polish, perfumes, and confections of various sorts. It is a matter of wonder that workers in factories where it is employed do not frequently suffer.

#### PERSONAL.

HIS MAJESTY THE KING has been graciously pleased to confer the title "Royal" upon the Sanitary Institute, the headquarters of which is at the well-known Parkes Museum, Margaret Street, London, and to signify his pleasure that the Institute be known henceforth as the Royal Sanitary Institute.

DR. F. W. MOTT, F.R.S., will deliver the Bowman Lecture of the Ophthalmological Society to-morrow, (Thursday) at 9 p.m., on "The Visual Cortex." The Nettleship Medal will be presented to Mr. Priestley Smith before the lecture. All members of the profession are cordially invited to attend.

THE gold medal of the British Medical Association has been awarded to Sir Constantine Holman for his distinguished services to the British Medical Association, through the South-Eastern Branch, on the Central Council as treasurer and as vice-president; and, further, for his life-long and successful labours for the improvement of the financial conditions of the medical charities.

A COTTAGE hospital has been opened at Tredegar by Lord Tredegar, situated in the park which he had previously presented to the town.

PROFESSOR ROBERT KOCH is to be the recipient of the Nobel Prize in medicine this year.

It is announced that the new Maternity Hospital for Belfast will be opened by Countess Grosvenor on November 7th.

DR. T. ORME DUDFIELD read a paper on "The Need of Sanatoria for Consumptives, and How it may be Supplied," at a special meeting of the Charity Organisation Society on Monday last, at 4.30 p.m., at the Royal United Service Institution.

THE opening demonstration of the winter session of 1904-05 at the Brompton Hospital for Consumption will be given by Dr. Percy Kidd to-day (Wednesday), at 4 p.m., on "Some Points in the Prognosis and Treatment of Pneumonia."

It is announced that his Majesty the King has been pleased to appoint Dr. Bertram C. A. Windle to be president of Queen's College, Cork, in the room of Sir Rowland Blennerhassett, who has resigned. Dr. Windle is at present Dean of the Medical Faculty and professor of Anatomy and Anthropology in the University of Birmingham.

THE current issue of the *Leys Fortnightly*, the magazine of the Leys School, offers congratulations to an Old Leysian, Mr. J. P. Mummery, F.R.C.S., L.R.C.P., on his appointment as one of the honorary medical

(a) *Journ. Amer. Med. Assoc.*, October 1st, 1904.

staff of King Edward VII.'s Hospital for Officers; also Assistant-Surgeon to the North-Eastern Hospital for Children, Hackney Road.

DR. M. M. LOUDON, of Arundel, last week received a handsome presentation from friends and patients on the occasion of his wedding.

ON the 28th ult. the foundation-stone of the new building of the Liverpool Infirmary for Children was laid by the Lady Mayoress, Lady Hampson.

LAST week the remains of the late Lady Dilke were cremated at Woking.

PROFESSOR KOCH has returned to Berlin from Paris, where he had gone to thoroughly inspect the Pasteur Institute, for which he is said to be full of praise and admiration. He leaves for South West Africa in December.

SIR SQUIRE BANCROFT will distribute the prizes and deliver an address to the students of Charing Cross Hospital on Wednesday, November 23rd, 1904, at 4 o'clock.

AT a special meeting of the governors of London Hospital last week Dr. Cecil Wall was elected assistant physician.

DR. ST. AUBYN FARRER, on Monday last, presided over a most successful inaugural general meeting of the newly-formed association of Medical Diplomates of Scotland.

SURGEON-MAJOR GENERAL T. WALSH has been awarded a good service pension in recognition of his long and meritorious services in the Army Medical Department. During the past forty-six years, he has served in many parts of the world, taken part in several campaigns, and has been thrice mentioned in Despatches.

#### THE NEW PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

WM. J. SMYLY, M.D. T.C.D., F.R.C.P.

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND.

INAUGURAL ADDRESS OF THE ROYAL MEDICAL SOCIETY.—The winter session of the Society was opened on October 28th, by Sir James Crichton Browne, who addressed the Society on "The Tendency of Medical Education." It was just forty years, he said, since, as a fourth-year's student, he took possession of the Chair of the Society with feelings of exultation that had known no parallel since. Not the least momentous educational advantage the Society might exert was to keep alive some vestige of idealism among the members. It could not be doubted that the present tendency of medical education was towards materialism. By the very nature of his work the student was accustomed to submit everything to outward and palpable tests. He was nurtured on hard facts which tended, as Oliver Wendell Holmes, averred, to breed a despotic frame of mind in those wrapped up in them. He was in constant danger, unless strongly fortified by natural piety, of having his perceptions materialised and of losing in breadth what he might gain in concentration. Science, when so exclusively pursued, while it expanded the mind in some directions, contracted it in others. A large and varied culture was necessary for the full enjoyment and utilisation of life, a truth which was too apt to be lost sight of in these days of rampant specialism. Physiological and pathological study of the brain and nervous system tended more than anything else to materialise the student's conceptions. From the medical point of view it was convenient to speak of mental modification in terms of brain function, and this serviceable style of expression fostered a habit of thought, and so, more and more, the student was disposed to accept the teachings of leaders of revolt, who contemptuously dismissed their most cherished beliefs, hopes and aspirations, and taught that there was neither creative mind, future being, nor free will, and that life and consciousness were of inorganic origin. Haeckel, with his "Riddle of the Universe" had doubtless confirmed many students in materialism. Haeckel however, with all his subtlety, could not get rid of God, but merely substituted an inane fetish of his own which he labelled substance. Nor was he more successful in disposing of mind and convincing them that it was merely a mechanical function of that form of matter which he called psychoplasm. Like Bathybius, psychoplasm was being discredited by the progress of science. Though matter was the vehicle of mind, it was dominated, transcended, and moulded by it. To medical men a belief in the higher reality was a sustaining thought, amidst all the suffering and death through which their path must lead. This was a world of small cognition, but of mighty inference, and to the thoughtful the inference might dominate the cognition, and the things of faith be more real than those of sense. Materialism was a sorry creed negated by those universal human afflictions that would not be buried in the grave, and must, to the theologian, at least, have a motive and objective. Doubt was needful as a stage in the mind's progress, but it was no abiding place, and in scepticism there was no rest, for most sceptics were harassed by doubts of their own scepticism. Let them contemplate the brain, then, not as a mere collection of atoms or a mass of phosphorised fat, but as a psycho-active body, from which, as long as life lasted, a sheaf of emanation issued infinitely more mysterious than radium. There was the neuron, and behind it the psychon, and they must regard man, not merely as a material object among other material objects, but as a "reasonable soul and human flesh subsisting." The meeting was presided over by Dr. C. J. Shaw, senior president of the Society, and was closed by a cordial vote of thanks to Sir James Crichton Browne.

STUDENTS' RESIDENCE AT EDINBURGH MATERNITY HOSPITAL.—The Milne Murray Lodge, though it has been occupied for some two months now, was only formally opened on the 28th ult. The opening ceremony

was attended by a large company, including Sir John Tuke, M.P., Sir Halliday Croom, Sir John Sibbald, and many other medical men. Professor A. R. Simpson, in declaring the institution open, alluded to the importance of the work which the students had to study. The Lodge accommodates twelve students; it is situated in Lauriston Park, immediately behind the Maternity Hospital.

#### BELFAST.

**ROYAL VICTORIA HOSPITAL.**—The winter session at the Belfast Medical School was opened last week with an address given at the Royal Victoria Hospital by Mr. Andrew Fullerton, F.R.C.S.I. The speaker dwelt first on the necessity of a good preliminary training in chemistry, biology, and physics, for the student who wished to make the most use of his hospital experience. Comparing the new hospital with the old one, he said that the public were inclined to show their appreciation of the new by abusing the advantages it afforded, and in this connection he touched on the general question of hospital abuse, both in Ireland and England. The necessity for attention to clinical work was impressed on the students. It might be all very well, Mr. Fullerton said, to read up the account of a muscle or of a physiological experiment in a book, but it was a poor business to read the symptoms of a disease when they could actually see them at the bedside of the patient. On the other hand, how pleasant it was to read up a disease, the symptoms of which one had just studied in the ward. The laziest and most indolent student could hardly fail to get a fair idea of the more common surgical and medical ailments if he attended the hospital extern and wards diligently, even if he did not read a line. Dealing with club and dispensary practice, Mr. Fullerton said that it had been the ruin of the medical profession, and the fate of the club doctor was often too miserable for description. The matter would not be satisfactorily dealt with till young medical men refused to take posts vacated by those who had been sweated and imposed upon beyond endurance. At the conclusion of the address a vote of thanks was moved by Professor Sinclair, seconded by Professor Byers, and supported by Dr. Henry O'Neill, and passed with enthusiasm by the students.

**THE NEW WORKHOUSE SANATORIUM.**—At their last meeting the Belfast Guardians had under consideration the constitution and pay of the nursing and medical staffs of the new sanatorium at Whitehouse. They propose that the salary of the resident medical officer be £12 per annum, with rations and apartments, but that instead of making a permanent appointment, they should give the post to any one of the medical officers of the city workhouse who desired it, for a period of six months at a time. The salary of the visiting medical officer is also fixed at £120 per annum, and it was arranged that Dr. Hall, the senior medical attendant of the workhouse, should be asked to take this post temporarily. One of the guardians, Dr. Ritchie, thought that they could not expect Dr. Hall to devote much time to the work at such a small salary, and proposed that he should be paid £200, increasing to £300; but the proposal did not find favour with the majority.

**THE SMALL-POX OUTBREAK.**—During the first ten days of October no fresh cases of small-pox were discovered in Belfast, but since then there have been seventeen cases, including nine last week. Four of the cases were removed in one day from a house in the Sandy Row district of Belfast, and two more cases from the same house shortly after; four of these six cases being unvaccinated children. Two other unvaccinated children in the same street have contracted the disease and have been removed to the hospital at Purdysburn, where eight of the seventeen patients now under treatment are unvaccinated! Nearly all the cases at present under treatment belong to the same connection, the adults of the different families working together. The general type of the disease is comparatively mild, but the unvaccinated cases are, as usual, severe, and at least one is likely to prove fatal.

## Correspondence.

### THE VERNON HARCOURT INHALER.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—In your issue of October 26th you publish a letter from an anonymous correspondent in reference to a death which recently occurred under chloroform at University College Hospital. One usually ignores unsigned letters, but as you extend your editorial ægis over your anonymous correspondent's letter, and say rightly that one should not shrink from adverse criticism, I will answer the two queries contained in the communication in question. First, the "Vernon Harcourt" inhaler was not used on the occasion referred to. In the second place, I am informed by the house-surgeon who administered the chloroform that he was compelled to use a Schimmelbusch's mask with a drop bottle as the seat of operation rendered the employment of a closely-fitting mask, such as that attached to the "Vernon Harcourt" inhaler an impossibility. As a matter of fact, I regret that he did not use the last-named apparatus during the induction of narcosis, for I am convinced that it affords the best chance of safety for patients who, like the poor woman who died, run so grave a risk during the induction of anaesthesia, owing to antecedent disease and habits. Narcosis having been established, the open method could for the convenience of the operation have been adopted.

I am, Sir, yours truly,

DUDLEY BUXTON.

82, Mortimer Street, Cavendish Square, W.

### THE TREATMENT OF INOPERABLE CANCER.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—With reference to the communication from Mr. George E. Keith, published in your last issue, reverting to my paper on the treatment of "inoperable cancer," I desire, with your permission, to make one or two comments thereon. It is necessary in the first place to point out to your readers my position with respect to Mr. G. Keith and the treatment which I have advocated in my paper. In 1902 I commenced treating cases of uterine fibroid by means of hypodermic injections of iodipin. My procedure and details of treatment were freely made known to Mr. G. Keith, and published. Having learned all I had to teach, I was startled later to hear he had introduced a mixture for hypodermic use in cases of cancer. I have no wish to deprive Mr. G. Keith of any credit which may be his due, but I was certainly aware at the time of hypodermic medication in cancer. Subsequently, on inquiry as to the precise composition of his mixture, he refused to divulge its nature except on the promise that I would not reveal it till he was ready for publication. Acting on this promise I have neither revealed it nor tried it.

I have only one word more to add, viz., that Mr. G. Keith's mixture was neither chian turpentine nor soap solution, and I therefore still claim that the administration of chian turpentine by hypodermic medication is original, as far as I am concerned, and in justice to myself and others, I would ask Mr. G. Keith to make known the mixture he told me of.

I am, Sir, yours truly,

JOHN A. SHAW-MACKENZIE.

42 Green Street, Park Lane, W.  
October 27th, 1904.

## Obituary.

**JAMES BURN RUSSELL, B.A., M.D.Glas., LL.D.**  
SCOTLAND has lost a distinguished member of the medical profession in the person of Dr. James Burn Russell, M.D., LL.D., medical member of the Local Government Board for Scotland, and formerly medical officer of health for Glasgow, who died suddenly in Edinburgh at the age of sixty-seven. He was formerly physician-superintendent of the City of Glasgow Fever Hospital, assistant medical officer of the Town's

Hospital, Glasgow, and medical officer of health for the city. In 1885 the University of Glasgow conferred on him its honorary LL.D. degree; in 1891 he carried off the Stewart prize of the British Medical Association, and in 1899 won the Bisset Hawkins Memorial Medal of the Royal College of Physicians, London. He was a Fellow of many learned societies. Dr. Russell had paid much attention to the question of the housing of the poor and had written largely on public health. While his loss to public health work in Scotland will be great, it will be little less felt by a large circle of friends and fellow workers.

ANGEL MONEY, M.D.LOND., F.R.C.P.

THE news of the sudden death of Dr. Angel Money, at Sydney, will be read with regret by those who knew him formerly in London. He entered as a student of the Medical Faculty of the University of London in 1874, when his brilliant qualities soon brought him into prominence, and his ability and enthusiasm, coupled as they were with untiring industry, soon attracted attention. He became house physician and house surgeon at University College Hospital. Subsequently he was appointed physician to out-patients and house-surgeon to the General Lying-in Hospital, Lambeth, where he did good work in investigating the condition of the heart in the later months of pregnancy. He was later appointed medical registrar to the Hospital for Sick Children, Great Ormond Street, and assistant physician in 1885. In 1887 he became assistant physician and assistant professor of clinical medicine, University College Hospital. He worked hard and wrote much, among his books being "A Treatise on Disease in Children"; he was a constant attendant and a frequent speaker at the medical societies in London, when he was attacked by illness. He was compelled to resign his appointments, and in 1892 he went out to Sydney. Here again he acquired a considerable practice. His health gave way again, and a career of brilliant promise was cut short.

DR. ROBERT H. MOORE, F.R.C.S.

WE regret to have to chronicle the death of one of the oldest medical men, and probably the oldest dental surgeon in Ireland, Dr. R. H. Moore, of 29, Uppen Merrion Street, Dublin, who died on October 24th, in his eighty-ninth year. Robert Henry Moore studied his profession at the School of the Royal College of Surgeons in the early thirties, and in 1844 obtained the Fellowship of the College. He was at an early stage in his career apprenticed to Mr. Samuel McLean, who was one of the most important dental surgeons of his day. So earnestly did he devote himself to the practice of the special branch of his profession which he had selected, that not only did he enjoy a large practice, but also filled the post of Surgeon-Dentist in Ordinary to several successive Lords-Lieutenant of Ireland. He also represented the dental profession on the Council of the Royal College of Surgeons, and when the Incorporated Dental Hospital was established he was elected its senior consulting dental surgeon. Dr. Moore lived a strenuous active life, and when he retired from active practice he had well earned the rest he obtained. He leaves many friends to mourn his loss.

### SPECIAL REPORT OF THE CENTRAL MIDWIVES BOARD.

MEETING HELD OCTOBER 27TH, 1904.

The President, Dr. CHAMPNEYS, in the chair.

THE President began by proposing a vote of condolence with the widow and family of Mr. Heywood Johnstone, saying the Board would always remember him as a genial and practical helper in all its concerns. The vote was unanimously carried. Among minor business it was discussed whether a certified midwife acting as nurse under a doctor was bound to give notice to the authorities, the President remarking that a midwife might be one month in Yorkshire and the next in London.

Mr. Ward Cousins argued that sometimes a midwife was "practising"—i.e., conducting—the case alone, and sometimes not.

The President considered a midwife acting under a doctor to be only a glorified monthly nurse, but if she were resident and practising in a place she ought to give notice to the authorities, which was then put to the vote and carried.

It was also agreed to discuss *in camera* three cases of a legal nature at an extra meeting to be held on November 3rd. Applications for approval as institutions for the training of midwives under Section 3 were considered from the Secretary of State for War on behalf of hospitals for soldiers' wives and children at Chatham, Portsmouth, and Woolwich, it being decided to grant such permission in due proportion to the number of births, as these institutions, in common with another, the Withington Infirmary, had clearly not understood the rule of personal supervision, but had allowed several students to claim attendances at one lying-in.

The final consideration of the examination scheme was then proceeded with, which, in its amended form, we publish in another column.

Mr. Ward Cousins next inquired whether a midwife could give a notification of a still birth to the authorities, the President replying that the question would be decided by the General Medical Council.

Miss Paget then moved that the period of the approval of any certified midwife (duly qualified so to act) for the purpose of signing Forms III. and IV. under Rule C. I (2) shall expire on March 31st next following such approval, but may be renewed from time to time for the period of one year as often as the Board shall think fit. Provided that no approval granted by the Board before March 31st, 1905, shall require renewal before March 31st, 1906, which was carried. The date of next meeting was fixed for November 24th.

### Medical News.

Royal Army Medical Corps (Volunteers).

THE following appointments have been officially gazetted:—Surgeon Lieutenant-Colonel J. Cantlie, M.B., 7th Middlesex (London Scottish) Volunteer Rifle Corps, and Honorary Lieut.-Colonel Commandant Maidstone Companies, Royal Army Medical Corps (Volunteers), is appointed to the Honorary Colonelcy of the Companies.

Royal College of Surgeons of Edinburgh.

At a meeting of the College held on the 19th ult. the following gentlemen, having passed the requisite examinations, were admitted Fellows of the College:—Wilfrid Allport, M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Birmingham; Simon Alexander Ballantyne, M.B., Ch.B.Edin., Abington; Donald Duff, L.R.C.S.E., Glasgow; Harold Dyer, M.R.C.S.Eng., L.R.C.P.Lond., South Croydon; Duncan Campbell Lloyd Fitzwilliams, M.B., Ch.B.Edin., Edinburgh; James Graham, M.B., C.M.Edin., Cockermonth; Donald Alexander Hingston, M.D., Laval, Montreal; Christopher Tredwell Holford, M.R.C.S.Eng., L.R.C.P.Lond., Birmingham; Edwin Henry Irwin, M.B., C.M.Edin., Co. Monaghan; Robert Bathgate Johnston, L.R.C.S.E., Edinburgh; Nicholas John Kalomiris, M.R.C.S.Eng., L.R.C.P.Lond., London, S.E.; James Graham McBride, M.B., Ch.B.Edin., Edinburgh; Daniel Sayre Mackay, M.D., C.M. McGill, L.R.C.S.E., Nova Scotia; Mrigendralal Mitra, L.M. & S., Punjab, Calcutta; William Newlands, M.B., Ch.B.Edin., Edinburgh; Robert Ramsey, M.B., Ch.B.Glasg., Glasgow; Athelstan John Henton Saw, M.D., Ch.B.Camb., Perth, West Australia; Fred William Sumner, M.B., Ch.B., Camb., M.R.C.S.Eng., L.R.C.P.Lond., Preston, Lancs.; John Charles Venniker, M.D., Ch.B.Durh., M.R.C.S.Eng., L.R.C.P.Lond., London, W.; David Llewelyn Williams, L.R.C.S.E., Edinburgh; and Oswald Samuel Wraith, L.R.C.S.E., M.D.Durh., Darwen, Lancs.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been awarded the Diploma of the Society (L.S.A.), entitling them to practise medicine surgery, and midwifery: A. A. Angelis, W. H. A. Elliott, B. H. Hirst, E. E. Tucker.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a distinctive *Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES or LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**CONTRIBUTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**Mr. A. E. HOLDEN.**—Your communication was received as the journal was on the press.

**Mr. FLEETWOOD.**—In reply to your queries: (a) the subject is a complicated one and has not been finally determined. (b) The value particularly attached to the employment of Mellin's Food is its exceptional richness in maltose, the analogue of lactose. (c) Dr. Haig's work ought to be consulted.

**E. L.**—See reply to Mr. Holden.

### "PARTING IS SUCH SWEET SORROW."

Nature removes our teeth and hair;  
And while we think it most unfair,  
Harder it is to understand  
Why we should part with Prostate Gland!  
Perhaps Appendix in addition  
Before we're summoned to Perdition.  
The Prostate Gland! The Prostate Gland!  
You hear of it on every hand,  
"Appendicitis filled a page,  
Now Prostatitis is the rage,"  
And while the gland supply is ample  
Just make an extract, Try a Sample!  
It really might be found to answer  
Perchance a real cure for Cancer.  
"Man wants but little here below"  
When Prostate and Appendix go.—A.D.

**SKERRINGTON.**—There is not the slightest danger in any ordinary X-ray exposure conducted by a skilled medical man. At the same time it has been well known for five or six years that operators are liable to intractable injuries that may assume a malignant type. Here again the careful operator may readily ensure himself against injury by taking ordinary precautions. The newspapers have rediscovered a recent history, and we regret the names of medical men should be involved.

**W.C.S.**—It is impossible to discuss matters that have not a direct or indirect medical interest in the columns of a medical journal, however interesting such matter may be from a philosophical point of view. The immense ground covered by the scientific and the politico-social and economic phases of medical life renders the pressure on space more and more exacting.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 2nd.

**OBSTETRICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. H. H. Dauber and others. Paper:—Dr. H. R. Spencer: Three Cases of Cancer of the Cervix complicating Labour in advanced Pregnancy, the Patients remaining well Eleven, Eight and a half, and Eight Years after High Amputation of the Cervix.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. J. Cantile: Clinique. (Surgical.) 5.15 p.m. Dr. D. Williams: The Therapeutics of some Common Ailments.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (North-Eastern Fever Hospital St. Ann's Road, N.).—2.30 p.m. Dr. H. Cuff: Demonstration on Fevers.

THURSDAY, NOVEMBER 3rd.

**RONTGEN SOCIETY** (20 Hanover Square, W.).—8.15 p.m. Ordinary General Meeting. The Presidential Address.

**NORTH-EAST LONDON CLINICAL SOCIETY** (Tottenham Hospital, N.).—4 p.m. Clinical Cases.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutobinson: Clinique. (Surgical.) 5.15 p.m. Dr. W. Ewart: The Treatment of Acute Heart Disease and Loss of Compensation.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fileroy Square, W.).—5 p.m. Lecture: Mr. H. Barwell: Principles of Treatment of Laryngeal Cases (illustrated by cases). (Post-Graduate Course.)

FRIDAY, NOVEMBER 4th.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY** (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Paper:—Dr. Turner: The Treatment of Scarlet Fever, Diphtheria, and Enteric Fever at the South-Eastern Hospital.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY** (West London Hospital, Hammersmith, W.).—8 p.m. Clinical Evening. Cases will be shown by Dr. F. S. Abraham, Dr. A. E. Russell, Mr. A. Baldwin, Mr. B. L. Paton, Mr. G. Simpson, and others.

**SOCIETY OF ANAESTHETISTS** (20 Hanover Square, W.).—Discussion of the Vernon-Harcourt Chloroform Inhaler (opened by Mr. E. Wilson); Dr. D. Burton, Dr. Silk, Dr. Proby-Williams, Dr. Blumfeld, and others will take part.

**LARYNGOLOGICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—5 p.m. Cases, Specimens, &c. will be shown by Mr. E. B. Waggett, Mr. P. de Sauti, Dr. E. F. Potter, Mr. A. H. Cheate, Mr. A. Roberts, Dr. Nelson, Mr. H. B. Robinson, and others.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Dr. L. Lack: Clinique. (Throat.)

## Vacancies.

**Royal London Ophthalmic Hospital** (Moorfields Eye Hospital), City Road, E.C.—Senior House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications immediately to Robert J. Bland, Secretary.

**Warnford Hospital, Leamington.**—House Surgeon. Salary £100 per annum, with board, washing, and apartments. Applications to G. T. Poole, Secretary.

**City of London Asylum, near Dartford, Kent.**—Medical Superintendent. Salary £800 per annum, with unfurnished house, coal, light, laundry, and garden produce. Applications to Charles Fitch, Clerk to the Visiting Committee, Guildhall, E.C.

**Nottingham Children's Hospital.**—House Surgeon. Salary £100 per annum, with board and residence. Applications to A. F. Kirby, Secretary, Albion Chambers, King Street, Nottingham.

**Peckham House Asylum.**—Second Assistant Medical Officer. Salary £150 per annum. Application to the Resident Licentiate, Peckham House, Peckham, S.E.

**St. Mary's Hospital for Sick Children, Plaistow, E.**—Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry. Applications to Percy J. Glenton, Secretary.

**Wolverhampton and Midland Counties Eye Infirmary.**—House Surgeon. Salary £70 per annum, with rooms, board, and washing. Applications to the Secretary.

**Royal Portsmouth Hospital.**—Senior House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to J. E. Neil, Secretary.

**Smedley's Hydropathic Establishment, Matlock.**—Resident Physician. Salary £150 per annum. Applications to Dr. Harbison, Smedley's, Matlock.

## Appointments.

**BUCHANAN, P.S., M.B., &c.**—Outdoor Midwifery Department, Glasgow Public Dispensary.

**GRANT, W. F., M.Sc., M.B., Ch.B. Vict., M.R.C.S., L.R.C.P.**, Junior House Surgeon to the Birkenhead Borough Hospital.

**KALONIRIS, N., L.R.C.P. Lond., F.R.C.S.**, Clinical Assistant to the Chelsea Hospital for Women.

**NAIRN, A. BALFOUR, L.R.C.P. & S. Edin., L.F.P.S. Glasg.**, Pathologist and Assistant Medical Officer to the West Riding Asylum, Wakefield.

**ORMEROD, HENRY LAWRENCE, M.D., B.Ch., E.U.I., L.R.C.P. Lond., M.R.C.S.**, Medical Officer for the Henbury District by the Thornbury Guardians.

**PAINE, ALEXANDER, M.D., B.S. Lond., D.P.H.**, Joint Pathologist with Dr. D. J. Morgan to the Cancer Hospital.

**PARSONS, WALTER BROCK, M.R.C.S., L.R.C.P. Lond.**, Assistant Anaesthetist to the Royal Dental Hospital, Leicester Square.

**ROSS, J. A., M.B., Ch.B. Edin.**, Junior House Surgeon to the Croyden General Hospital.

**ROYWELL, WILFRED F., M.B., B.Ch. Vict.**, Third Assistant Medical Officer at the Manchester Union Infirmary, Crumpsall.

**TAYLOR, E. GRAHAM, M.B., &c.**, Gynaecological Department of Glasgow Public Dispensary.

**WALL, E. C. B., M.D. Lond.**, Assistant Physician at the London Hospital.

**WALLACE, A. TAYLOR, L.D.S.R.C.S. Edg.**, Honorary Dental Surgeon to the Convalescent Home at Western-super-Mare.

## Marriages.

**GILLIAT—DUKE.**—On October 27th, at St. Nicholas's Church, Bathampton, Somerset, Algernon Edward Gilliat, eldest son of Mr. Algernon Gilliat, of Stoke Poges, Bucks, to Eva Marjory, only surviving daughter of the late Dr. Douglas Duke, of Cannes, France, and of Mrs. Duke, of 1 Sydney Place, Bath.

**LONDON—BRIGGS.**—On October 27th, at the Parish Church, Britwell Salome, Marcus Moore London, M.D., of Tarundel, Sussex, to Florence Mary, only daughter of the late Hickson Briggs, of Ialeworth, and of Mrs. Biggs, of Britwell Priory, Oxfordshire.

## Deaths.

**MACKENZIE.**—At Foo-Chow, A. E. Maud, the beloved wife of Rev. Marcus Mackenzie, M.B. (C.M.S., Fuh-ning, China), and daughter of the late Rev. J. A. Aston, of St. John's, Deptford, aged 29.

**WILLIAMS-FREEMAN.**—On October 28th, at Weyhill, Andover, Lorna Augusta, infant daughter of John P. Williams-Freeman, M.D., aged 10 months.

### CANCER OF THE LARYNX. (a)

By SIR FELIX SEMON, C.V.O., M.D. Berlin,  
F.R.C.P. Lond.

Physician-Extraordinary to his Majesty the King.

MR. PRESIDENT AND GENTLEMEN.—The keynote of the observations which I shall have the honour of addressing to you was struck in a discussion on malignant disease of the larynx at the meeting of the American Laryngological Association in 1902, when Dr. Bryson Delavan stated that it was time "that the discussion of these subjects upon theoretical grounds should give place to careful studies of what was actually being accomplished by practical men."

It is a matter of history that the case of the late German Emperor represents the turning point of modern knowledge of cancer of the larynx. Until then, that knowledge had been incomplete and unsatisfactory. Very little was known about the early symptoms and early laryngoscopic appearances of the disease, and as a rule its existence was only recognised when it was in an advanced stage. Up to 1878 many cases were in such circumstances treated by thyrotomy, an operation which, though positively ideal in early stages is quite insufficient, as we now know, when the disease is more advanced. The results were naturally disastrous and led, after Paul Bruns' sweeping condemnation in 1878, (b) to almost complete abandonment for a time of thyrotomy in malignant disease of the larynx. The more severe forms of radical operation—total and hemi-laryngectomy—enthusiastically welcomed when first introduced, did not at once justify the hopes which had been raised, and in the early "eighties" of the last century the outlook for the unfortunate patient afflicted with laryngeal cancer was grave in the extreme.

There can be no doubt that the sympathetic interest with which the whole world followed the melancholy course of the Emperor Frederick's illness gave a sudden and universal impetus towards a closer study and better understanding of that formidable disease. First came the revival of the deplorable doctrine of the late Mr. Lennox Browne, (c) *viz.*, that benign laryngeal growths were specially liable to undergo malignant degeneration after intralaryngeal operation. This was followed by the publication of my "Collective Investigation," (d) undertaken with the help of most of the prominent laryngologists of the world, to test the truth of this assertion. The material thus collected enabled me not only to show the complete want of foundation of Mr. Browne's contention, but also to establish more definitely than had hitherto been done the differential diagnosis between benign and the early stages of malignant neoplasms of the larynx, and to discuss fully

the position and relative importance of the microscopic examination of intralaryngeally removed fragments of new growths for the differential diagnosis between the benign and malignant forms.

Before the report of the "Collective Investigation," which was published in instalments, had been concluded, Professor Bernhard Fraenkel, of Berlin, published his remarkable paper, "Laryngeal Cancer, its Diagnosis and Treatment," (a) in which, besides studying the histological characteristics of laryngeal cancer, he advocated anew in suitable cases the treatment by intralaryngeal operation, which he had first proposed in 1886. In reply, I lost no time in urging in the concluding chapter of the "Collective Investigation" some of the objections which seemed to me obvious against adopting intralaryngeal instrumentation as a suitable means of combating laryngeal cancer. About the same time Mr. H. T. Butlin (b) inaugurated a new era in the treatment of intrinsic cancer of the larynx by showing that owing to our diagnostic progress it was possible to obtain the same results in early cases by thyrotomy which had previously been believed to be unobtainable by anything short of hemi-laryngectomy. From this time onwards the remarkable national cleavage took place which characterises our present situation. Previously to the Emperor's illness, however imperfect and unsatisfactory our knowledge of laryngeal cancer may have been, there had at any rate been no national differences, and the opinions with regard to diagnosis and treatment which dominated our actions were, whether right or wrong, entertained by the whole laryngological world. From 1889, all this changed. A number of German laryngologists, headed by Jurasz (c) and following Fraenkel's lead, advocated, and still advocate, intralaryngeal operations in apparently suitable cases of malignant disease of the larynx. They have found allies in France, in Spain, and in America, whilst apart from myself, the employment of intralaryngeal surgery in cases of malignant disease of the larynx has been deprecated by Schrötter, Chiari, and Paul Bruns. On the other hand, my own statements concerning the diagnostic importance of some of the early signs of laryngeal cancer have met, I am afraid, with but little attention in other countries besides Great Britain, and, similarly, it is astonishing to observe how little impression the reports of British successes obtained by thyrotomy in suitable cases seem to have made upon the minds of operators on the continent of Europe and in America.

In 1900, Dr. John Mackenzie read at the meeting of the American Laryngological Association a paper entitled "A Plea for the Early Naked-eye Diagnosis and removal of the Entire Organ, with a Neighbouring Area of Possible Lymphatic Infection in Cancer of the Larynx." The contentions of this remarkable paper, with but few exceptions, run straight against all established teaching. The author demands naked-eye diagnosis of malignant disease of the larynx in its early stages to the complete exclusion of the intralaryngeal removal of a fragment for the purposes of microscopical

examination. The latter he rejects *in toto*, and urges against its employment that the removal of tissues for examination subjects the patient to the dangers of auto-infection at the point of incision and to metastasis elsewhere, that it stimulates the local growth of cancer, and that the method is often inconclusive, misleading, and sometimes practically impossible. In the further course of his observations he emphatically condemns thyrotomy, and his teaching culminates in the statement that there was only one rational method, in the majority of cases at least, of dealing with cancer of the larynx: "Early total extirpation of the entire organ with its tributary lymphatics and glands, whether the latter be apparently diseased or not, is the only possible safeguard against local recurrence or metastasis." When I first read this paper I was not inclined to take it seriously. Throughout it substitutes theory for practice to such a degree, threatens hypothetical dangers which experience has shown practically to be non-existent, totally disregards the actual results obtained by trustworthy observers, and indiscriminately demands extreme measures where experience has shown milder ones to suffice, that I considered a detailed refutation unnecessary, and therefore referred to it in a chaffing spirit in the course of some lectures I delivered in 1901. (a) But, to my regret, the matter has not ended there. In 1902, Dr. Mackenzie, in a further discussion on cancer of the larynx, which took place at the meeting of the American Laryngological Association, declared that he abided by his views, and since then I have been credibly informed that these views have exercised a perturbing influence upon not a few minds on this side of the Atlantic. I shall therefore content myself with discussing the four most important of Dr. Mackenzie's assertions only. These are the following: (1) That the naked-eye method of diagnosis is a comparatively neglected method; (2) that the microscopical examination of a fragment intralaryngeally removed is to be totally rejected; (3) that early total extirpation of the entire organ with its tributary lymphatics and glands, whether the latter be apparently diseased or not, is the only possible safeguard against local recurrence or metastasis; and (4) that thyrotomy is not up-to-date surgery, is in direct defiance of the rules that should govern us in the treatment of laryngeal cancer, and is a reversion to, and a resurrection of, a method of procedure that was discredited and abandoned half a century ago.

1. According to Dr. Mackenzie, the naked-eye diagnosis is a comparatively neglected method. What is the real state of this question? In the introduction I have referred to my endeavours to promote the knowledge of the subjective signs and laryngoscopic appearances of the early stages of malignant disease of the larynx. Having in 1886 (b) and 1888 (c) enumerated in two communications of mine some of these signs, I reverted to the subject at greater length in the "Collective Investigation" I undertook in 1888 and devoted an entire chapter of my report to a systematic description of the minute details which in a number of cases had enabled me to diagnose laryngeal cancer at a comparatively early period. This description has, so far as I know, remained up to this moment the last word on the subject. When I returned eight years afterwards to this question (d) I stated, even more emphatically than I had done in 1888, *verbatim* as follows: "Unfortunately, with the only exception of those cases in which it is possible to intralaryngeally remove a fragment of the new growth and to establish its epitheliomatous nature by the help of the microscope, *not one single sign* in the early stages of malignant neoplasm of the larynx is in itself so characteristic that it establishes with absolute certainty the malignant nature of the formation. The contour, the seat, the condition of

the surface, the colour of the new growth itself, the condition of the neighbourhood, the mobility of the vocal cord, the age of the patient, other subjective symptoms, they all may and will assist the experienced eye in making the diagnosis, particularly when several of them *jointly* raise such suspicion, but all of them are not *absolutely* characteristic in the earliest stages, and the possibility of a mistake is not excluded in some less characteristic cases." Butlin, too, has correctly characterised the situation when he said in his introductory paper on the occasion of a discussion on the early radical treatment of laryngeal cancer (e) that "we were still in this position, and were likely to remain in it for a good many years to come. That we must admit that there are three classes of cases: The first, in which anyone and everyone can make the diagnosis; the second, in which the better instructed or more experienced make it and others do not; and the third class in which the conditions are so obscure that no one can make the diagnosis, unless the larynx is opened and in some of which it is even then difficult to be sure of the nature of the disease."

That, gentlemen, is, I maintain, a true description of the present state of matters. However much we all desire—and I do not yield to Dr. Mackenzie in that respect—further to advance our clinical knowledge of the early stages of laryngeal cancer, we have not made diagnostic progress since 1888. Although, no doubt, in the great majority of cases an experienced observer will make the correct diagnosis of intrinsic cancer of the larynx in its early stages from clinical signs alone, the possibility of occasional errors is anything but excluded. They have occurred in the practice of other experienced observers and they have occurred in my own. And what is most important in view of Dr. Mackenzie's light-hearted advice—*viz.*, to perform extirpation of the whole larynx with its tributary lymphatics and glands on the strength of naked-eye diagnosis alone—is the fact noticed by others (b) as well as by myself, that when an error in diagnosis is committed it is more commonly on the side of regarding an innocent growth as a malignant one than a malignant growth as an innocent one. In the present connection, speaking on the strength of large personal experience, I only wish to say that I maintain most strongly that our clinical knowledge of these stages is not yet perfect and that occasional diagnostic mistakes are unavoidable. Dr. Mackenzie himself admits that "there is unfortunately no solitary unequivocal symptom or laryngoscopic sign of cancer," and seems to allow that "after weighing carefully all the facts of the case in our possession a reasonable doubt may remain as to the diagnosis." Just so; but what is the logical conclusion, gentlemen, to which all the foregoing drives us? Surely that it is the positive and imperative duty of every observer to resort to *every* method of diagnosis that could possibly help him in establishing a certain diagnosis before radical operation of any kind is performed.

2. Here we come to the second of his contentions—*viz.*, to the total rejection of the microscope as a diagnostic help in cases of suspected laryngeal growth. His reasons for opposing intralaryngeal removal of a piece for microscopic examination are that such removal "subjects the patient at once to the dangers of auto-infection at the point of incision and to metastasis elsewhere, that it stimulates the local growth of cancer, and that the method is often inconclusive, misleading, and sometimes practically impossible."

I fully admit the possibility of auto-infection in laryngeal cancer, particularly when the surface opposite to an ulcerating new growth should have lost its covering epithelium. But when this theoretical possibility has been admitted and when the practical question is now asked: How often has such inoculation been actually observed? I am happily in the position to state that so far as my literary knowledge goes, there are only three cases recorded as examples of local auto-infection in laryngeal cancer. Seeing the

enormous number of cases in which during the last forty years fragments of growth have been intralaryngeally removed for purposes of microscopic examination, this one fact suffices for me, and, I venture to think, will suffice for most men of a practical turn of mind, to dismiss Dr. Mackenzie's alarming assertion as too theoretical to come within the range of practical politics.

Seeing the help that the microscope has so often given me in difficult cases of this kind, I personally have no hesitation in following my great teacher's, the late Professor Traube, principle, that, when one is confronted with two evils one ought to select the smaller. In other words, I am absolutely in favour of microscopic examination whenever this is possible.

But Dr. Mackenzie says, thirdly, that "the method is often inconclusive, misleading, and sometimes practically impossible." Here I must again refer to the "Collective Investigation" and express my regret that our author should have so entirely disregarded the lessons taught therein. Within the limits of this address I cannot enter more fully upon this question. It has been thoroughly threshed out in the "Collective Investigation" and its result has been summarised in the following conclusions:—

3. The first of these is that early total extirpation of the entire organ with its tributary lymphatics and glands, whether the latter be apparently diseased or not, should be performed as the only possible safeguard against local recurrence or metastasis in practically all cases of malignant disease of the larynx as soon as the diagnosis had been established. It is true that in the last part of the paper it is admitted that there may be "exceptional" cases in which a "very small growth, distinctly circumscribed, remote from the middle line, and not of a specially malignant type, may possibly be removed with safety" by extirpation of half of the larynx and the lymphatics on the corresponding side. But even this admission is made grudgingly, and from the whole tenor of the paper and the context of the paragraph in question it is perfectly obvious that operation for cancer of the larynx, to be in the author's opinion complete, ought to embrace nothing less than removal of the whole organ with its lymphatic vessels and glands. This recommendation is based upon the author's contention that the severity of surgical interference, when dealing with cancer, ought to be the same in whatever part of the body a malignant growth may be met with. This contention again shows a profound disregard of practical experience. Whilst no sane person has ever asserted that cancer is one thing in one part of the body and another thing in another, both careful clinical observation and the results of surgical interference have incontestably shown that—other circumstances being equal—both the severity of the required interference and recurrence after operation depend to a degree, the practical importance of which can hardly be over-estimated, upon the question of the primary localisation of the malignant new growth. Every surgeon when called upon to give a prognosis and to operate in a case of epithelioma of the lip, the ear, or the penis, knows that the prognosis with regard to recurrence is infinitely better, the amount of interference required much smaller, than in a case of epithelioma of the tongue or pharynx, or in a case of cancer of the breast. These facts are so fundamental and so generally admitted that I hardly think a single surgeon will be prepared to deny them.

After a full review of the operative side of the question, the lecturer proceeded: From the foregoing observations I trust you will have seen that I am certainly not an extremist, and I may further tell you that, acting upon my views, I have, in the course of the last year alone, myself sent three patients suffering from advanced malignant disease of the larynx, and in whose cases operative interference had been refused by British surgeons, to Professor Gluck. Even the fact that unfortunately two of them have within a few months after operation developed recurrence would not deter me from consenting to, or even advising on, future operation in similar circumstances. But one thing,

gentlemen, I think, is absolutely certain—*i.e.*, that such grave operations ought only to be undertaken under two conditions—(1) that the diagnosis was absolutely certain; and (2) in the event of there being no possibility of saving the patient by a less mutilating operation.

With regard to the first of these conditions it is one of the most surprising omissions in Dr. Mackenzie's paper that he should not have referred by one single word to the terrible situation which would be created for both the patient and the surgeon in the event of so serious an operation as that proposed by him being undertaken on the strength of a mistaken diagnosis.

Four methods here come into consideration—intralaryngeal removal, subhyoid pharyngotomy, thyrotomy, and hemilaryngectomy. With regard to the intralaryngeal method, I have unfortunately had to differ on so many points from Dr. Mackenzie that it gives me genuine pleasure to say that at any rate I am at one with him when he says that "operation for laryngeal cancer through the mouth, done almost universally to-day, it seems to me should no longer come within the range of serious consideration." I reject intralaryngeal operations in cases of laryngeal cancer—which, by the way, I believe to be not nearly so universally practised as Dr. Mackenzie assumes—not because I deny the possibility of curing a few patients by this method, but because, in my opinion, the game is not worth the candle.

The second contingency—subhyoid pharyngotomy—can be dismissed in very few words. Although I have lately heard privately that better results have been obtained more recently, I am waiting for confirmation of these tidings before I see my way to recommend adoption of this method in cancer of the larynx.

4. But how about thyrotomy? Here we come to the last and perhaps the most extraordinary of Dr. Mackenzie's assertions. As already stated, he unreservedly condemns this operation in the following terms: "Thyrotomy with curettement or removal of all apparent (visible) parts diseased is not up-to-date surgery, is in direct defiance to the rules that should govern us in the treatment of cancer, and is a reversion to, and a resurrection of, a method of procedure that was discredited and abandoned half a century ago." I know that Dr. Mackenzie is absolutely incapable of deliberately making a misleading statement, but in speaking of thyrotomy as being not up-to-date surgery, as being in direct defiance of the rules that should govern us in the treatment of cancer, and being a reversion to, and a resurrection of, a method of procedure that was discredited and abandoned over half a century ago, he none the less creates as wrong an impression in the mind of the uninitiated reader as if he had intended to produce it.

In the introduction to this paper I have reminded you that thyrotomy for laryngeal cancer was in 1878 discredited and subsequently practically abandoned because in those days advanced and therefore *a priori* unsuitable cases were subjected to an operation the *technique* of which at that time was anything but methodically developed. If twenty years afterwards, with improved *technique*, that operation has again been resorted to in a class of cases totally different from those in which it has been unsuccessfully employed at a previous period, it surely is not fair to describe a progressive and beneficial development of that character as "a reversion to, and resurrection of, a method of procedure that was discredited and abandoned half a century ago." If during that period its true nature be recognised, and an operation be performed which not merely removes the tumour itself but a sufficient area of healthy tissue in all directions round it, the patient has a reasonable chance of being lastingly cured. Such an operation is modern thyrotomy as first suggested by Mr. Butlin. Fifteen years' experience has shown that by its employment the disease can be completely and lastingly eradicated, and to describe it as an "incomplete and therefore hazardous and unsurgical" operation is wide of the mark.

And now as to the results of the operation so much deprecated by Dr. Mackenzie. Last year at Swansea I

reported from my own practice twenty thyrotomies with or without removal of small fragments of cartilage in cases of undoubtedly malignant disease of the larynx, with nineteen recoveries, two quite doubtful recurrences, and one death. (a) I am now—irrespective of the incomplete operation which had to be repeated—in possession of the notes of twenty thyrotomies performed for undoubted malignant disease of the larynx between 1891 and 1904 with one death, two doubtful recurrences, and seventeen lasting cures, bringing the percentage of successful cases in my own practice within that period up to 85 per cent. In addition to the twenty cases just named, I have performed three further thyrotomies in the course of the present year. All three patients have made an excellent recovery. In one of them, however, in which the patient had, in spite of my urgent advice, unduly postponed the operation, recurrence has, unfortunately, taken place, and I have had to perform partial laryngectomy on the eve of my departure for America. The other two cases are of too recent date to be included as yet in the class of permanently cured cases.

From the foregoing facts it will not surprise you if I most warmly recommend the performance of thyrotomy in suitable cases of intrinsic laryngeal cancer.

Permit me earnestly to repeat my advice that thyrotomy should be performed only when the new growth is still limited to the intrinsic region of the larynx, is still circumscribed, is not too extensive, and does not infiltrate too deeply, and that in such circumstances a sufficient zone of healthy tissue should be included in the area to be removed *everywhere* in sufficient distance from the new growth. Should it be found, in the course of operation in a case which seemed on laryngoscopic examination to fall under this category, that the disease is more extensive than had been presumed from laryngoscopic appearances, the operator must not hesitate to extend his operation into hemilaryngectomy, or if both sides of the larynx should be involved into total extirpation. It is only by the observance of this cardinal rule that thyrotomy will gain the place which is due to it among radical operations for cancer of the larynx.

The second request I have to make is this: Whilst thyrotomy is still on its trial everywhere except in Great Britain, let me ask you to proceed strictly on the lines suggested by Mr. Butlin and myself. I do not believe in the finality of our present *technique*, and I willingly admit that it may be possible, when once thyrotomy has everywhere gained its place among recognised operations for laryngeal cancer, to improve upon the method of operation by means of which we have obtained such satisfactory results. But whilst the operation is still on its trial do not complicate matters by prematurely introducing modifications.

The only remaining operation to be discussed is hemilaryngectomy, or partial extirpation of the larynx. Already last year at Swansea I expressed my conviction that partial extirpation of the larynx will come to be more rarely performed in proportion to the diagnosis of malignant disease being arrived at more and more early, when thyrotomy will suffice. I should not offer any objection to extirpation of the corresponding lymphatic glands even if apparently unaffected in cases of hemilaryngectomy for cancer, although, as my third case shows, even that measure, when once metastasis has actually occurred, does not give the patient a guarantee against recurrence. That such extirpation should, as a matter of duty, be performed in cases of hemilaryngectomy if the glands are in the least shotty or visibly enlarged goes without saying, but in such cases the prognosis anyhow is unfortunately very doubtful.

And now, gentlemen, I am at the end of my task. I have, as promised, nailed my colours to the mast of

(a) I take this opportunity to correct a slip of the pen which I just find is committed in my paper published in Fraenkel's "Archiv" in 1897. It is stated there (p. 419) that I had lost "two" patients from thyrotomy performed by myself. On reference, however, to my original article (*loc. cit.*) it will be seen that one of those cases (Case 6 of the tables) was not one of thyrotomy, but of partial extirpation of the larynx.

practical experience as against theoretical possibilities. At the same time I trust I have succeeded in showing you that the principles upon which my views are based are not purely empirical, and are in all points in concord equally with the experiences of practice and with the achievements of science. Let me summarise what I have endeavoured to establish under the form of the following theses, which may serve as a basis for the discussion which I understand is to follow the reading of this address:—

1. It is of the greatest importance that the diagnosis of laryngeal cancer be made at the earliest possible moment. For this purpose it is most essential that the still prevailing notion—*vis.*, that malignant disease of the larynx is from the first attended by all sorts of grave constitutional symptoms—be completely eradicated and that the attention of the general practitioner should again and again be drawn to the fact that there are no more promising cases for radical operation than those in which the disease is at first manifested by nothing else than by obstinate hoarseness, occurring, without any apparent cause, in middle-aged and elderly persons.

2. Clinical diagnosis arrived at from the history and subjective symptoms of the case, from laryngoscopic examination, from accessory circumstances of importance, such as the patient's age, &c., has reached a certain degree of perfection, and enables us in a good many cases to make a correct diagnosis at an early stage of the disease; it is, however, by no means absolutely perfect, and occasional mistakes occur even in the practice of those most experienced.

3. In these circumstances clinical diagnosis ought, whenever possible, to be confirmed before radical operation of any kind is undertaken, by the intralaryngeal removal and microscopic examination of a fragment or fragments of the new growth. This, however, should only be done if the patient previously consents to immediate radical operation being undertaken in the event of the microscope confirming the clinical diagnosis. Should this be the case, the practitioner's position will have been materially strengthened. The microscope, however, is by no means infallible in these cases. Should its evidence be negative or inconclusive the intralaryngeal removal and microscopic examination of fragments should either be repeated, if necessary, several times, or, if the clinical symptoms do not warrant postponement, exploratory thyrotomy should be undertaken.

4. The intralaryngeal method is from its very nature unsuitable for the radical removal of malignant new growths of the larynx.

5. Subhyoid pharyngotomy, apart from being applicable in a very small number of cases only of malignant disease of the larynx, is still *sub judice* with regard to its advisability in such cases.

6. Thyrotomy, if undertaken in suitable cases, and at a sufficiently early period, and if performed on the modern lines which experience has shown to be successful, is a perfectly ideal operation in intrinsic cancer of the larynx.

7. Hemilaryngectomy comes into question only when it is found after opening the larynx that mere thyrotomy will not suffice. When performed it may be accompanied by removal of the tributary lymphatics, even if apparently not diseased.

8. Total laryngectomy should be exclusively reserved for extrinsic, and for those cases of intrinsic cancer in which both sides of the organ are affected, and in which the disease has proceeded too far to be eradicated by milder measures. When performed it should be accompanied by the removal of the laryngeal lymphatics on both sides of the neck.

If the adoption of these principles should meet with your approval, gentlemen, there will be an end to the deplorable schism which has of late separated the surgeons and laryngologists of various countries with respect to the diagnosis and treatment of malignant disease of the larynx, and we may justly hope that in striving shoulder to shoulder we shall advance science and benefit our patients.

## A HELPFUL AGENT IN THE TREATMENT OF SURGICAL DEBILITY.

By J. S. PURDY, M.B., C.M.Aberd., D.P.H.Camb.,  
Of London.

THE condition of depression or exhaustion occurring in surgical patients is so common and oftentimes so rebellious to treatment that any measure which seems to offer material help in that direction is welcomed eagerly by surgeons generally. Many surgical cases manifesting obvious and striking signs of impoverishment of blood, nutrition, or nervous force owe their origin and continuance to one or more conditions amenable to operative procedures only. Equally true is it that perhaps even a larger number of cases do not regain their normal standards of health with satisfying rapidity after operations, or are in a debilitated state which necessitates postponement of operations, and it is in these cases that surgeons are compelled to seek the aid of tonic and reconstructive drugs.

The object of this communication is to record, briefly, general and specific observations upon this point made during the past two years in the surgical wards and out-patient departments of two large metropolitan hospitals, where cases are sufficiently numerous and facilities ample to obtain valuable clinical data upon the subject. In the management of these cases, so many extraneous and contributing factors enter that it is sometimes difficult to determine how much of the benefit is due to the medicines administered, and how much must be attributed to hygienic measures, suitable dieting, careful nursing, &c. Nevertheless, these factors are more or less constantly present, and, with the added guidance of experience, one is enabled to form fairly accurate deductions as to the rôle played by drugs in the sum total of general improvement. These points have been given due consideration, and after two years' comparisons of various tonics and reconstructives in pre- and post-operative surgical conditions we believe we are justified in stating that iron vitellin must be considered as a valuable aid in the treatment of what may be termed surgical debility. British physicians are proverbially conservative in accepting innovations in any phase of practice, and particularly in the matters of new drugs and new operations; perhaps such new departures are scrutinised with more care in this country than elsewhere, and we are not given to accepting the statements of others without personal verification. In this connection, it is interesting to note that several of the most distinguished and conservative British physicians—Murrell, Phillips, Tirard, Carpenter and others—have published careful scientific studies of iron vitellin which substantiate that this drug has physiological effects of a nature which endow it with unique value in certain clinical conditions. Our observations corroborate those already published, although ours were confined almost entirely to cases of a surgical nature.

The cases in which we have administered iron in this form may be divided into four general groups:—

1. Surgical convalescence.
2. Anæmia from hæmorrhage.
3. Preliminary to operations of a more or less serious character.
4. In the class of out-patients suffering from immediate or remote effects of syphilis, tuberculosis, osseous necrosis, &c.

The points about the clinical effects of iron vitellin which seem to be worthy of emphasis are illustrated best by brief notes of cases in which much of the improvement noted was clearly ascribable to the action of the remedy.

A robust woman, æt. 23, presented herself with an acute and especially virulent attack of gonorrhœa, involving the entire genito-urinary tract, including the uterus. Disobedience of house rules as to rest and

local treatment led in ten days to the development of chills, fever and delirium. Examination revealed signs of double pyosalpinx, which demanded immediate operation. She was curetted, the uterus packed, abdominal cavity opened and both pus tubes removed. Pelvic peritonitis rather diffuse was present. Her condition was grave and for the ensuing five days, with a temperature of 104°, and pronounced symptoms of sepsis, her recovery was considered doubtful. On the sixth day after operation, her temperature began to fall, and on the tenth day had reached normal. The toxæmia seemed to have ravaged the blood particularly. Her lips and conjunctivæ were colourless, the skin waxy-green, prostration very marked. Hæmoglobin was 20 per cent., red blood corpuscles 1,700,000. Stomach intolerant of food and medicines. She was given koumiss, broths, as much as she liked, and iron vitellin in tablespoonful doses, three times daily. One week later, hæmoglobin was 45 per cent., red blood corpuscles, 3,000,000. Two weeks later hæmoglobin 52 per cent., red blood corpuscles, 3,200,000. Three weeks later hæmoglobin 65 per cent., red blood corpuscles, 3,700,000; colour, strength, appetite, digestive power, all strikingly improved. Five weeks after the operation, and two days before she left the hospital, her hæmoglobin was 87 per cent., red blood corpuscles, 4,200,000. The rapidity of the action of iron vitellin in restoring the blood constituents in this case was probably due to the condition known as "iron hunger," brought about by the rapid destruction of the blood elements by the toxins.

Toxic anæmia similar to the case just cited is by no means uncommon, and occurs in practically all cases where the systemic infection has been at all marked. The difficulty in treating these patients with food and medicine directed to restoring the wasted tissues is increased by an irritable, non-retentive condition of the stomach. In all of the cases treated thus far with iron vitellin in no instance has the remedy been rejected, nor has it ever induced signs of irritation of the stomach or intestines. We have been very much struck with this fact in the post-operative treatment of four cases of septicæmia in which gastric irritability was most marked. Two of these cases were sepsis following criminal abortion, one case of pyothorax, and one large superficial abscess of the liver, in all of which operations were performed; systemic infection followed with consequent toxic anæmia, and in which iron vitellin was used successfully in combating the anæmia and adynamia.

We have made observations also of the effect of the remedy upon the blood in twelve cases of severe exsanguination as the result of accidental hæmorrhage. Eight of these occurred during labour, four of which were cases of placenta prævia; the remaining four cases were the result of severe arterial hæmorrhage in consequence of lacerated wounds. Of the total of twelve cases, in ten of them iron vitellin restored the blood constituents to normal in periods varying from two to five weeks; in two cases, both debilitated women, the blood constituents remained below the normal standard after six weeks' treatment.

Surgical debility, so called, is a rather complicated pathological condition in which anæmia is entirely subsidiary to very obvious disturbance of general nutrition. In this class of cases tonic and reconstructive drugs are employed, as a matter of routine, with widely-varying degrees of success. No one drug or combination of classes of drugs prove uniformly efficient, and the choice of remedies is usually decided by a consideration of the individual indications, not the least of which is the condition of the gastro-intestinal tract. From our observations, extending over a period of two years, we believe that iron vitellin gives perhaps the best percentage of good results as a remedial factor in the general hygienic measures applied in the treatment of surgical debility. The following is a case in point:—

A woman, æt. 27, married, had recurrent attacks of appendicitis of moderate severity, extending over a

period of three years. She had also prolapsed ovary, adherent tube on right side, dysmenorrhœa. For two years she had steadily failed in general health and had lost 20 lbs. in weight. She was operated on in January, 1903, the enlarged, inflamed appendix, the right tube and ovary, removed. Recovery from the operation was uncomplicated, but the patient remained pallid, weak, nervous and irritable, had anorexia, nausea and vomiting. Five weeks after the operation, when the above symptoms were present, she was placed on a partial rest-cure régime, was given massage, electricity, careful diet, and a tablespoonful of iron vitellin three times daily. At that time her hæmoglobin was 55 per cent., red corpuscles, 3,000,000. Under the combined therapeutic measures applied, she gradually gained in strength and flesh, her stomach became receptive and retentive, and the nervous irritability disappeared. Four weeks later she had gained 10 lbs. in weight, had no troublesome symptoms, hæmoglobin was 80 per cent. and red corpuscles 4,300,000, and she was given permission gradually to resume her wonted occupations.

The following case, belonging to a different category, is illustrative of another type of cases in which we have used the remedy to obvious advantage:—

A man, æt. 61, plethoric, considerably adipose, had been under treatment for two years for prostatic enlargement, with retention of urine and gradually increasing attacks of cystitis. For two years his general health had failed, and for six months it was deemed necessary to operate, but pallor, lassitude, inability to take sufficient nourishment, and presence of chronic dyspepsia, and red blood corpuscles 2,550,000, hæmoglobin 55 per cent., indicated too great general disturbance. He was sent to Aix-les-Bains in May, 1903, where his dyspepsia yielded satisfactorily to the régime practised. The only tonic used was iron vitellin, a tablespoonful in water after meals and at bed-time. After five weeks' stay at the baths his general condition has become remarkably improved, and he returned home on June 15th, when his hæmoglobin showed 82 per cent., red blood corpuscles, 4,550,000. On June 22nd, the Bottini operation was performed, and the patient made a satisfactory recovery, and is at present in excellent health.

Our observations upon the use of iron vitellin among surgical out-patients are chiefly of value in determining its general tonic action rather than specific effects upon the blood, as with but few exceptions systematic blood examinations were either impossible or deemed unnecessary. In syphilitic patients, of the secondary and tertiary stages, we were able to confirm the statements already published, that iron vitellin is a valuable adjunct to antisyphilitic treatment, in that it has a beneficial action upon the anæmia so constantly present, and improves the general nutrition, which is usually below par. These effects were noted in the anæmia accompanying the eruption of secondary syphilis and in the anæmia and malnutrition of the gummata and necrosis of the tertiary stage.

This general tonic action of the remedy is perhaps its chief claim for consideration, and is the first effect to strike the attention of both the surgeon and the patient. It is particularly noticeable in the management of tuberculosis of the glands, bones and joints when the remedy is administered conjointly with appropriate surgical treatment, and judicious application of such valuable aids as good food, &c.

Another class of surgical out-patients in which we have used iron vitellin with conspicuous success is illustrated by the following brief notes:—A nurse had become very much run down in consequence of a whitlow and onychia, the thumb-nail having been removed. She was given iron vitellin, a tablespoonful three times daily. Her appetite improved, pallor gradually disappeared, there was no constipation, and she rapidly regained health and strength.

Another case was that of a man who was very much debilitated and was suffering from repeated crops of boils. Arsenic and calcium sulphide were given without appreciable effect. A fortnight's treatment with

iron vitellin effected a striking improvement in the general health with coincident disappearance of the boils.

This communication must be looked upon as a purely clinical one, with no ambition to deal with the scientific phases of the questions involved in a study of the broad problems of anæmia and malnutrition, whether they be of surgical or medical cases.

These questions properly fall within the sphere of the hæmatologist, the physiological chemist, and the physician. It seems, however, to the practical surgeon that in dealing with these conditions the pure scientist is too prone to unduly emphasise one feature—for instance, systematic blood examinations—when called upon to determine the effect of any given plan of tonic treatment, medicinal or physical. Far more important is it in forming such opinions to consider the effect upon the blood constituents as but a subsidiary feature, and to give due weight to the effect of treatment upon the appetite, the ability to digest and assimilate food, and upon the general nutrition as revealed to the physician by a glance or by inquiry, unassisted by the precise methods of investigation, such as blood examinations. In other words, the practical value of such treatment is in proportion as it produces visible improvement in the general condition of the patient.

### CLINICAL NOTE ON MEDITERRANEAN FEVER.

By CHARLES HELFIELD, M.A., M.B., M.S.

HAVING taken some interest in the etiology and pathology of Mediterranean fever, and having had the opportunity of living on the coasts of the Mediterranean, I watched all cases of fever that fell to my *confrères* and my lot to treat as attendant or consultant; I therefore beg to offer a word to its effect.

Out of perhaps 300 cases attended by us I discovered that the micrococcus melitensis of Bruce was not only conveyed by the air, but it was capable of being introduced into the system by food and drink. Bacteriological examinations corroborated our suspicions in finding the bacilli in water kept in jug or filter from which the patient under our care had drank before he or she complained of any symptoms—*i.e.*, headache, giddiness, vomiting, or a profuse perspiration, and in six cases out of ten the micrococcus could be found in fresh fruits, such as figs and prickly pears (*opuntia*). This same disease, though endemic in Egypt and the Red Sea, appears under different aspects, forms, symptoms, and course, and cannot in any way be compared to those occurring at Malta, Naples, Tunis, and Sicilian ports. At Malta the variety generally seen can be easily diagnosed by the splenic enlargement, its relapses, constipation; and the temperature reaches up to 104°. but generally it is undulatory and always with profuse sweating; the first symptom is diarrhœa. Delirium is very often present during the first fortnight's illness, and the patient feels very irritable. The complications are arthritis, tenderness over the spleen and liver, neuralgia, and, in rare instances, orchitis. In Sicily the variety is similar to that of Malta fever, but it tends to be more malignant in its type; the onset is sudden and the mortality is nearly 5 per cent. In Egypt or at the Red Sea ports, the variety is intermittent, of a short duration—five weeks the utmost—the symptoms are those of ordinary pyrexia and the mortality is 0.5 per cent.

What I desire to illustrate is the urgency of obtaining the reaction in every case of fever that

falls to the practitioner's lot, just to ascertain the quality of the fever; the reaction can be had in all varieties, and in every case on the fourth day. As for the treatment, rest is essential; the patient must get at short intervals plenty of nutritious fluid diet, the skin should be sponged at least four times a day with brandy or whisky and water, no alcohol should be given internally unless urgently required, and the drug that proved with us most beneficent and curative was kaïrin in 5-grain doses, with 3 of oleum eucalypti three times a day, with a hypodermic injection of strychnine, 1-50, once a day. Quinine is hurtful, and other drugs and intestinal disinfectants useless; constipation must be treated with an enema of castor oil and warm water daily.

Mediterranean fever seldom attacks people living in the country, or the lower classes, and when it does it is of a very short duration, but it is most liable to attack the better classes, town people and those in busy life.

### A NEW UTERINE MOP.

By S. JERVOIS AARONS, M.D., M.R.C.P.

THE difficulty and amount of time wasted in removing the wool from the ordinary Playfair's probe after it has been used led me to try and devise some means by which the mop might be more easily and quickly removed. It occurred to me that a cap of some absorbent material which would fit over a conical probe would serve the purpose, and such a cap, or mop, I have had made; this slips over a conical or tapering metal probe, and is held in position by a small bayonet catch, which effectually prevents it from twisting round or leaving the probe.

The dry mops weigh 13 grains (.79 grammes); after being used they weighed 39 grains (2.5 grammes); they are therefore sufficiently absorbent for the purpose.

The advantages over the ordinary Playfair's probe are:—

1. Ease and rapidity of dressing the probe.
2. Ease and rapidity of removing the mop after use.
3. Both mops and probes are easily sterilised.
4. The tapered part of the probe, being made of plated copper, can be bent to any desired shape.

The caps are put up in sterilised packets of four, or they may be had separately but not sterilised.

Both probe and caps were made for me by the Galen Manufacturing Co., Ltd., Wilson Street, New Cross Road, S.E., and my thanks are due to them for so successfully carrying out my suggestions.

#### The Cancer Hospital, Brompton.

WE are asked to announce that Lady Ludlow has kindly promised to open the new nurses' home erected in the hospital grounds on November 14th, at 3 p.m. The nurses at present are accommodated at the top of the hospital building in cubicles. The new home will provide separate bedrooms for each nurse, and a separate sitting-room for the sisters and nurses. The cost of erecting and equipping the home is about £5,500, but the committee feel that the expenditure is justifiable bearing in mind the arduous duties nurses at such a special hospital have to perform.

## Out-Patient Departments.

### TOTTENHAM HOSPITAL.

*Dermatological Cases under the Care of G. NORMAN MEACHEN, M.D., M.R.C.P.*

CASE I.—*Tar-Acne in a Psoriatic.*—The patient was a young man, æt. 19, an ex-postman, who said he had suffered from psoriasis since early childhood. He did not seek advice so much for this complaint as for a troublesome eruption around his shoulders. The history was that he consulted a chemist upon his own account a year ago for his chronic skin disease, and obtained from him some crude tar ointment, which he had been vigorously rubbing into the skin of his back. From previous experience he had learned that tar was "good for psoriasis." His grandmother had suffered from the same affection, but no other members of the family were affected. There was no history of rheumatic fever. His general health was good.

On examination, several typical lesions of psoriasis, in varying stages of evolution, were seen upon the trunk and limbs, but the most noticeable thing was a profuse papulo-pustular eruption about the shoulders and interscapular region. Interspersed between the papules were a large number of comedones. The face was clear, but there were several scaly places in the scalp.

Dr. Meachen remarked that acne-like eruptions were not infrequently seen in those who worked with tar and pitch, but it was not at all common to meet with true acne picealis as a result of tar medication in psoriasis. The application of the old-fashioned pitch plaster sometimes led to erythema and even to dermatitis, owing to the continuous local action of a mild irritant. This youth had been applying tar ointment daily for a twelvemonth without any medical advice under the impression, which was a very common one, that the more energetically he rubbed in the medicament the quicker he would be cured. It might, perhaps, be questioned why the acne should only have appeared upon the shoulders and not upon the limbs or other parts of the body, for he had applied the ointment everywhere. It must be remembered, however, that the severest cases of acne were often seen upon the back and interscapular region, these parts, together with the face, being the seat of election for the disease. Pathologically speaking, the lesions were produced through a blocking of the sebaceous ducts with tar, the presence of which acted as a local irritant, leading to inflammatory changes within the follicles and dilated portions of the ducts. Furunculosis was also seen as a result of the external application of tar.

A weak sulphur lotion was prescribed for the back together with the compound sulphur ointment, while a mild creolin ointment was ordered for the scaly patches upon the limbs. For the scalp the ung. hydrarg. ammon. was prescribed.

CASE II.—*Canities following Alopecia Areata.*—A little girl, æt. 8, was brought with several large patches of white hair upon the scalp. A year previously she had been treated for alopecia areata, but she had ceased to attend the out-patient department for some months. Shortly before the hair fell out she had an attack of scarlet fever, during which time the mother said the hair was not cut off. She had had no other illnesses.

On inspection the child presented a remarkable appearance, nearly one-quarter of the left side of the scalp being covered with silvery white locks. The adjacent hair was dark brown in colour. The eyebrows and eyelashes were normal. The general health was good, though the child was of an excitable disposition.

Dr. Meachen pointed out that the growth of hair which occurred upon an alopecic patch was generally of a somewhat paler tint than that which was lost, but it was distinctly uncommon for actual grey hair to appear, especially in a young child. The appearance

of the well-known downy growth upon the previously smooth and billiard ball-like area was always a most hopeful sign, and with the progress of time pigment began to be deposited within the hair shafts. The whole question of the production of pigment was rather complicated, since its visibility depended not only upon its absolute quantity, but also upon the degree in which air-bubbles were present between the cells of the cortical layers. A return to the natural colour was exceedingly rare, though cases had been recorded of such a transition.

As regards treatment, extensive canities might, in many cases, justify the systematic use of hair dyes. This little girl did not like going to school because the other children made fun of her. Silver nitrate in plain solutions of 1 to 3 per cent. was, on the whole, the best reagent for this purpose, though corrosive sublimate and pyrogallol were also largely employed. The parents of the child were strongly impressed with the idea that if the hair had been entirely shaved off during the attack of fever it would have come back the natural colour! There was a semblance of truth in this supposition, but clinical evidence was insufficient to enable us to state definitely one way or the other.

### British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

#### XV.—TORQUAY.

TORQUAY has won high repute as a health resort, and rightly holds a foremost place among winter stations. It is situated in a bay on the north side of Tor Bay, and has a south exposure. Its physical features are widely diversified and well fit it as a natural sanatorium. Comfortable shelter is afforded by the hills of the Torquay promontory, which rise to 448 feet. The geological formation is mainly Middle Devonian limestone and Lower Devonian grits and slates, and there is very little clay, and what does occur is of the nature of marl. Careful meteorological observations are taken twice daily at the Borough Station, which is admirably equipped with modern instruments of precision. [We are indebted to Dr. Thomas Dunlop, M.O.H. for Torquay, for a copy of his Annual Report for 1903, and much other information of service.] Mr. Frederick Marsh is the official meteorologist. The mean barometric reading for last year was 29.935. The temperature figures testify to the equability of the climate. The maximum mean was 56.7°; the minimum mean, 47.1°; the maximum and minimum mean, 51.9°; and the mean range, 9.6°. The duration of bright sunshine as recorded by the Jordan photographic twin instrument was 1,645.1 hours, and as recorded by the Campbell-Stokes standard instrument, 1,699.6 hours. The total rainfall amounted to 41.15, which was much above the average of recent years. The mean humidity was 78, as taken by Mason's hygrometer. During the latter part of the year west winds prevail, but in the spring the winds are chiefly easterly. The population is 33,810, the birth-rate, 15.8 per 1,000, and the gross death-rate 13.4 per 1,000; but on eliminating the deaths of visitors it comes out at 11.5 per 1,000. The water-supply, which is abundant and constant, is derived from upland surface gathering ground about fifteen miles from Torquay on the borders of Dartmoor. The water contains a small amount of lime and magnesia. The drainage system has been well designed and is maintained in a thoroughly efficient manner.

Torquay is admirably supplied with means for outdoor recreation, the public pleasure grounds and gardens, roads and foot-paths, are peculiarly well fitted for the needs of the health-seeker, whilst the immediate neighbourhood offers endless attractions as a centre for charming excursions. There is, however, a lack of those attractions under cover which are so sedulously catered for at Continental health resorts during the winter months, the absence of which at

Torquay is considered a serious drawback to those in search of amusement as well as health.

There are many excellent hotels and boarding-houses, and suitable apartments may always be obtained; but Torquay is in great measure a residential haven for the aged, and those invalided or injured in life's conflict.

Torquay is an admirable winter resort for those who, while enfeebled and unable to stand the exposure of most of our British stations, need a home residence with open-air life. The aged here find the burden of advanced life much lightened. The constitutionally delicate and those invalided by actual disease are afforded shelter and can maintain a hygienic life in comfort and carry on some form of work with pleasure and profit. Torquay is a very desirable winter centre for convalescents.

For many cases of pulmonary disease it provides conditions particularly alleviative. While it is undesirable for most incipient cases of phthisis it is well fitted for many chronic and advanced cases, particularly where the bronchitis involvement is conspicuous.

For elderly persons, the subjects of chronic bronchitis, emphysema, asthma, renal disease, and those requiring a comparatively warm, sheltered, equable climate, with opportunities for gentle exercise and quiet amusement, Torquay may be strongly recommended.

The hillsides are, of course, unsuited to many cardiac cases and subjects of vascular deterioration. For neurasthenics and those suffering from some forms of nervous derangement, Torquay during winter days can offer much that is desirable.

### Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.  
SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, OCTOBER 28TH, 1904.

H. C. EARL, M.D., in the Chair.

#### LYMPHATIC LEUKÆMIA.

PROFESSOR E. J. McWEENEY, M.D., read a paper entitled "Hæmatological Observations on a Case of Chronic and one of Acute Lymphatic Leukæmia." The first case was that of a man, æt. 55, admitted to the Mater Misericordiæ Hospital on September 2nd, suffering from splenic tumour, glandular enlargement and asthma. The most remarkable point in the previous history was an injury to left side of the abdomen, sustained last January, after which a sensation of discomfort developed—a possible traumatic origin being thus suggested. The cervical glands began to enlarge about Easter; the splenic tumour was first noticed in May. Blood-count on admission: R., 3,908,000; W., 163,000. Two days later the count was R., 2,848,000; W., 206,000. The differential count yielded polymorphs, 7.8; large mononuclears, 2.3; lymphocytes, 89.5; eosinophile and mast cells, 0 per cent.; a few normoblasts. On September 25th he developed lobar pneumonia, to which he succumbed on the 28th. There was no diminution of the total leucocyte-count consequent on the infection, and no increase of polynuclear elements in the peripheral blood on the day preceding death. The count on that day was R., 3,048,000; W., 332,000; percentage of mononuclears, 92.4. On the other hand, the blood taken from the lung at the autopsy twelve hours after post-mortem yielded 20.5 per cent. of polynuclears, as well as 0.5 per cent. of eosinophiles, and 3.5 per cent. of myelocytes, neither of which could be found in the peripheral blood during life. The spleen weighed 51 oz., was marbled with red and grey patches, and contained infarcts. Microscopically the trabecular system was much reduced, and the follicles obliterated by a uniform distribution of rather large mononuclear elements. Mitoses were hard to find; there was much iron-containing pigment; no giant cells. The glands were all much enlarged, highly vascular, distinction between follicles and sinus obliterated; mitoses

numerous. The marrow of the femur and humerus was of the normal character; that of the sternum was lymphoid. The liver (283 ozs.), kidneys and suprarenals showed typical lymphoid infiltration. The absence of blood change consequent on pneumococcal infection and the absence of the marrow change were the two most interesting features of the case.

*Case 2.—Acute Lymphatic Leukæmia.*—Patient was a boy, æt. 9; six weeks ill on admission, with moderate fever (100° to 101°); swollen glands, epistaxis and great prostration. The spleen was moderately enlarged, as was also the liver. Petechiæ on skin of abdomen and legs. Blood-count on admission: R., 1,898,000; W., 212,000; lymphocytes, large and small, being 98 per cent., with only 0.5 per cent. of polymorphs. Many of the lymphocytes showed signs of degeneration. On puncturing the skin through a droplet of Unna's polychrome methylene blue, their nuclei took the stain at once. No hard and fast line of separation could be drawn between small and large forms; the latter were very labile. Eosinophile and mast cells absent; normoblasts in small numbers, megaloblasts absent. The case ran a rapid course, dying nineteen days after admission from the uncomplicated disease. Blood-count on day of death was, R., 820,000; W., 723,000, 99.5 per cent. of which were lymphocytes. Several fields had to be searched before a polymorph was encountered. At the autopsy (three hours after post-mortem) the heart was distended with puriform blood. Thymus much enlarged; weighed 46 grammes. All the serous membranes covered with petechiæ. All the glands were moderately enlarged, soft and hyperæmic, but not confluent. Spleen (12 oz.) seemed almost normal save for the enlargement. Liver enlarged with enormous leukæmic infiltrations, the intralobular capillaries being literally plugged with lymphocytes. The kidneys were also most extensively infiltrated, and presented a very peculiar appearance. The lymphoid structures of the intestine were enlarged. The marrow of femur and tibia was hyperæmic and typically lymphoid (splenoid of Ziegler). It consisted almost entirely of large peculiarly lentish lymphocytes. Normoblasts frequent, megaloblasts few. Coarsely granular cells absent. The blood was examined bacteriologically ten days previous to death, 5 c.c. being withdrawn from a vein near the elbow and placed in a flask containing 500 c.c. of ordinary peptone broth, and incubated. No growth occurred, and after four days the blood cells seemed unaltered in the sediment. No trace of protozoa. This case afforded a highly favourable opportunity for the study of acute lymphæmia, as the autopsy was complete, and the tissues were fixed within five hours of death. The paper was illustrated by numerous microscopic preparations and coloured drawings, as well as by the specimens preserved at the autopsy.

PROFESSOR WHITE said that during the past year he had seen a case of the so-called spleno-medullary leukæmia in which there was apparently a direct connection between an injury and the disease. The patient fell down the hold of a ship, and hurt himself about the abdomen, but was able to work on for a fortnight, after which he went into hospital, and died in a few weeks of leukæmia. Another point in Professor McWeeney's case was the fact that the patient died so quickly of pneumonia. In one of the cases of leukæmia (common variety) he had seen, the patient, a woman, left hospital to go home, but missed her train and had to come back; she almost immediately developed a sharp attack of erysipelas, and died in twenty or thirty hours, showing the little resistance these patients have against infectious diseases. With regard to Hodgkin's disease, he did not think it was typical to find giant cells, and believed that when giant cells were found, we were probably dealing with some chronic infection, possibly tuberculous, instead of Hodgkin's disease.

Dr. CRAIG said that Professor McWeeney's cases rather upset the ordinary clinical teaching; for instance, he had been accustomed to teach that the increase of leucocytes was not so great in lymphatic as

in spleno-medullary leukæmia, but Professor McWeeney had said that in the acute case, at least, the red and white corpuscles were almost equal in number. Another point was that myelocytes were never present in lymphatic leukæmia. With regard to the case of acute leukæmia, he said it was of special interest because occasionally this disease occurs among children, and when the enlarged glands appear, they are supposed to have acute general tuberculosis.

Dr. EARL agreed with Dr. McWeeney as to the presence of giant cells in Hodgkin's disease, and he was certain that in the two or three cases of real Hodgkin's disease which he had examined he had found glands which were not those of tuberculosis.

Dr. McWEENEY, in replying, said that Professor White's observation as to the traumatic origin of a case of the spleno-medullary variety was very interesting, especially the short duration. The case would appear to have been acute myelæmia, which is very rare, whereas lymphæmia is sometimes acute, but he was not certain that any acute spleno-medullary cases had been recorded. With regard to his statement about the presence of giant cells in Hodgkin's disease, he based it on a report of the pathologist of the Ayer Pathological Laboratory, who had examined fifteen cases of the disease, and had met giant cells which it was easily seen were not tuberculous. They arose from some irritation of the large endothelial plates in lymphatic glands. In Germany Hodgkin's disease is called pseudo-leukæmia, as the patient looks as if he is going to have it. If the same cause produced Hodgkin's disease as produced leukæmia, then you would expect to find giant cells in the glands; but you do not. The explanation sometimes given is that in Hodgkin's disease, owing to some peculiarity of the capsule of the gland the greatly increased lymphoid cells in it and in the sides of the gland are so pressed on that they cannot get cut into the blood; whereas, if the same stimulus attacks a gland with soft sides, &c., the new lymphocytes do get out, causing leukæmia. With regard to Dr. Craig's remarks, he said it was very hard to stick to both the pathological and clinical aspects, but there could be no doubt that there are many cases of lymphatic leukæmia which give very large counts. Myelocytes were always present in lymphatic leukæmia, but they wanted looking for.

#### AORTIC ANEURYSM PERFORATING THE OESOPHAGUS.

Dr. MATSON showed a specimen of the above taken from a woman, æt. 50. History of alcoholism, but none of syphilis. Patient had been subject to attacks of rheumatic fever. Two years ago she had an attack of bronchitis, in which she expectorated a good deal of blood.

Dr. TRAVERS-SMITH asked, did the patient vomit blood?

Dr. CRAIG said that during the past year he had seen two cases. The first was a man complaining of symptoms referred to the stomach. He left hospital and came back in a dying condition with an aneurysm which ruptured into the oesophagus. The second case was one which he had met with seven years ago, and six years ago he read a paper stating that this patient with an aneurysm of the innominate artery had been cured. He then went about in good health, having only some dulness at the right of sternum and at the inner end of the right clavicle. During April of the present year this gentleman died suddenly in bed, and the post-mortem report showed that an innominate aneurysm was present. It was the size of an apple, and had walls an inch thick. The dilated portion still contained some blood in the centre. It was solid outside, and was adherent to the sternum, which it had half eaten through. In the descending part of the arch of the aorta was an aneurysm the size of a child's head. It had burst into the oesophagus, the latter, with the stomach, being full of blood. This patient had been cured of the innominate aneurysm, had gone about for seven years, and had grown fat and lived a healthy open-air life, but how long the second aneurysm existed was not known. This case was of interest from the sequel.

Dr. MATSON said, in reply, his patient vomited a considerable amount of blood, and there was a good deal of blood in her stomach.

**AORTIC ANEURYSM RUPTURING INTO PLEURA.**

Dr. GILLMAN MOORHEAD exhibited a case of aneurysm of the aortic arch, which had ruptured into the pleura. The specimen was obtained from a man, *æt.* 35, by occupation a sailor, and who had contracted syphilis ten years previously. The only symptom complained of was that of cough. Rupture occurred suddenly during sleep after the patient had been under treatment for four days. Almost the entire wall of the sac was necrotic, brittle and very thin, and only a small amount of soft clot was present. One hundred ounces of blood were found in the left pleural cavity. The curious point about the case was that rupture had not occurred while the patient was at work, as he had been up to within a week of his death.

**SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.  
MEETING HELD OCTOBER 27TH, 1904.**

The President, Dr. ARTHUR HALL, in the Chair.

Mr. PYE-SMITH showed the following cases and specimens:—(1) Large gall-stone removed on September 6th from the common duct of a woman, *æt.* 50, where it had become impacted subsequent to the removal, two and a half years before, of thirty-six stones from the gall-bladder, which was suppurating. The duct was sewed, a gauze drain being left in contact with it. No bile escaped, and the case did well. (2) Eight faceted gall-stones removed, on September 7th, from the common and hepatic ducts of a man, *æt.* 46, who had had severe jaundice for nine months. Six of the calculi were at the lower end of the common duct and two in the hepatic duct. They were all extracted by an opening at the level of the top of the duodenum. The duct could not be easily sutured and was drained through a stab wound, which closed in a month. The patient did well, but was not yet quite free from jaundice. (3) A fine, spiked, mulberry calculus, weighing 670 grains, removed, on September 20th, by suprapubic lithotomy from a man, *æt.* 28. (4) A small sequestrum of bone, about  $\frac{1}{8}$  inch in diameter, and a silkworm-gut suture, both of which were encapsuled in firm scar-tissue, removed on October 18th from the end of the stump of the forearm of a man, *æt.* 36, who had been shot in the hand two years previously. Immediate amputation had been performed (in Worcestershire), and the wound healed in six months, after two small pieces of bone had come away. The stump continued to be painful and tender, though the skin was in good condition. Two tender spots were found over two small hard lumps. After their excision the pain and tenderness disappeared.

Dr. SINCLAIR WHITE showed the following cases:—(1) A girl, *æt.* 7, with congenital double dislocation of the hip, on whom he proposed to operate by the open method. (2) A man, *æt.* 25, whose right upper extremity had been removed for a round-celled sarcoma of the upper arm by Berger's inter-scapular-thoracic amputation. The patient had made a rapid recovery. (3) A man, *æt.* 46, whose right scapula had been removed in March, 1900, for sarcoma. There had been no recurrence of the growth. He had a very useful arm, but was unable to elevate the upper arm beyond an angle of 45 degrees. In a more recent case still, better movements had been obtained by uniting the trapezius and levator anguli scapulae to the deltoid and the serratus magnus to the rhomboid muscles. The PRESIDENT showed cases of (1) aphasia, (2) Spinal progressive muscular atrophy, (3) multiple naevi of the face.

Dr. D. BURGESS read notes of a fatal case of cardiac hypoplasia in a young woman, and showed a child with intention tremors.

Mr. R. FAVELL showed (1) a specimen of the RUPTURED TUBAL GESTATION, together with an adherent vermiform appendix. The

patient, a married woman, *æt.* 32, married five years, never pregnant, regular twenty-eight days, lasting four days. The last period first week in April. Second week in May began to have a coloured discharge accompanied with frequent attacks of pain. The bloody discharge continued for three weeks, then for a week it ceased, coming on again and then continuing to the time of operation. By the vagina: A tense cystic swelling was felt in right lateral fornix, the uterus pushed over to the left. Section was done on July 1st, three months after her last period. The right tube was greatly distended with organised blood-clot, the embryo being found in the upper part of tube. The tube was ultimately adherent to the parietal and pelvic peritoneum, the vermiform appendix was inflamed and much thickened, being intimately adherent in its whole length to the tube. This was removed with tube.

**(2) DERMOID CYST OF OVARY ADHERENT TO VERMIFORM APPENDIX.**

The patient, *æt.* 32, two children, youngest *æt.* 8, had noticed swelling in lower abdomen for twelve months. Six weeks before operation she was seized suddenly with acute pain across the hypogastric region, accompanied with sickness and faintness. The swelling lay right across the hypogastrium, rising two and a half inches down the pubis. By the vagina: The tumour was found lying in front of the uterus and evidently adherent. On section, the dermoid was found to intimately adhere to the parietal peritoneum, to the uterus, the small intestine, and to the vermiform appendix; great difficulty was found in separating the adhesions. The patient made a good recovery.

**Dr. D. GRAY NEWTON read notes of a case of a GALL-STONE PRODUCING ACUTE INTESTINAL OBSTRUCTION.**

successfully removed by abdominal section, and showed specimen. The patient, a woman, *æt.* 66, eight years ago had her first attack of biliary colic, and then was free except for some dyspeptic symptoms till last year, when she had another attack, this time accompanied by jaundice which passed off in a week or so. The present attack occurred in May of this year, which was relieved somewhat by small and frequent doses of morphia, but early one morning (4 a.m.) she experienced an extra severe attack of pain, which did not last long, and afterwards the patient expressed herself as being more free from pain than she had done since the attack began. This will be seen to coincide in all probability to the passage of the gall-stone from the gall-bladder into the duodenum. Later on in the day she began to be sick, and unable to retain anything in her stomach, the vomit becoming faecal. After consultation with Dr. Sinclair White we both came to the conclusion that the obstruction was due to an impacted gall-stone, and advised an operation. The patient was conveyed to a surgical home. After the preliminary surgical toilette, the abdomen was opened in the middle line above the umbilicus, and a search made for the obstruction. A hard substance was felt in the intestine. That portion of bowel was brought to the surface, surrounded with gauze and opened in the longitudinal axis of the gut. Thereafter the stone was extracted. It weighed 2 drachms 6 grains, and measured in the long circumference  $3\frac{1}{2}$  inches, and in the short circumference 3 inches. The mucous membrane of the intestine was united by catgut, and the serous coat with fine silk. The deep portion of the abdominal wound was brought together by a continuous catgut suture; the superficial portion with silkworm-gut. After the operation the stomach was washed out with saline solution till the returning fluid was quite clear. The patient made an uninterrupted recovery.

**NORTH-EAST LONDON CLINICAL SOCIETY.  
CLINICAL EVENING HELD THURSDAY, NOVEMBER 3RD,  
1904.**

Dr. R. MURRAY LESLIE, President, in the Chair.

Dr. A. J. WHITING showed (1) a case of Acute

Anterior Poliomyelitis in a boy, *æt.* 9. The disease was of two months duration, of sudden onset, and all four limbs were affected. (2) An infant, *æt.* 2, with Spastic Diplegia of Cerebral Origin. The lower limbs were quite rigid and the hands were tightly clenched. The child was also distinctly microcephalic, and was very noisy in the ward. The case excited considerable interest and was discussed by several of the members. (3) A man with "Head-Tetanus," which had appeared after an injury. (4) A woman affected with Glosso-Labio-Pharyngeal Paralysis.

The PRESIDENT remarked that several cases of the latter disease which had come under his notice had met with a sudden fatal termination.

Dr. J. W. HUNT exhibited a man, *æt.* 59, with Cancer of the Neck. The history was that six months ago stiffness of the skin of the neck was observed, and a hide-bound condition of the cervical tissues upon the right side had gradually developed since that date. A small portion removed under chloroform showed microscopical evidences of malignant disease. The question of the possibility of relieving the pain by exposing the patient to the X-rays or to radium was discussed by several of the members.

Dr. NORMAN MEACHEN showed a young man, *æt.* 18, the subject of Tar-Acne. The patient, who was also affected with psoriasis, had applied tar to his back and shoulders somewhat vigorously during the past year.

Dr. R. B. MARJORIBANKS showed a skiagraph of an interesting deformity of the hand in a man, affecting the middle and ring fingers.

Dr. F. J. TRESILIAN (Enfield) showed a little girl with a Thyro-Glossal Duct Cyst, which was of long duration, but was said to have increased in size lately.

Mr. HERBERT W. CARSON remarked that the cyst was probably dermoid in origin, and he advocated excision in the submental region.

Mr. CARSON then exhibited two cases of Fractured Patella in men treated by operation. The fragments of the patella in both cases were not wired, but sutured with catgut in the peri-patellar aponeurosis in a circular fashion. The duration of the operation was considerably shortened by this procedure and the difficulties consequent upon the employment of silver wire were avoided.

Mr. CARSON also showed a man with a Primary Chancere of the Lower Lip.

Dr. T. D. MANNING (Hoddesdon) exhibited a man with an Acute Vesicular Eruption localised to the hands. The lesions consisted of tense vesicles, some of which had become purulent, and were situated upon the thenar and hypothenar eminences and dorsum of the hands. The central portion of the palms was only very slightly affected. The condition was strongly suggestive of cheiro-pompholyx, especially as the patient suffered from sweating of the hands.

Dr. MEACHEN, while admitting the close resemblance of the eruption to pompholyx, considered it to be a vesicular eczema, in view of the fact that the lesions were of small size, and grouped in profusion upon the dorsum of the hands and sides of the fingers, the central portion of the palms being practically spared.

Dr. D. M'CAKIE concurred in this view, the opposite opinion, namely, that the eruption was of the nature of a dysidrosis, being advanced by Dr. TRESILIAN.

The PRESIDENT showed a young woman, the subject of Chronic Pulmonary Tuberculosis, in whom a Pneumothorax had developed upon the left side. The patient was able to go about quite well, and, in fact, walked into the room.

Dr. G. P. CHAPPEL exhibited a specimen of the liver from a case of Acute Yellow Atrophy, which had recently been admitted into the Tottenham Hospital under his care. The patient was a girl, *æt.* 21, who had become infected with syphilis four months ago. Jaundice appeared soon afterwards, and vomiting, mental symptoms, and increasing weakness led to her admission into hospital. The liver dulness was greatly diminished, and death resulted from coma. At the autopsy the liver was very small, weighing only 25 ozs.,

and it presented all the characteristic features of the disease. Leucin and tyrosin crystals were found in the urine.

The PRESIDENT remarked that recent childbirth and an antecedent syphilis were not at all uncommon predisposing causes of this rare affection.

## THE CHILDHOOD SOCIETY.

MEETING HELD OCTOBER 27TH, 1904.

### THE PHYSICAL CONDITION OF THE WORKING-CLASS CHILDREN.

#### THE PROPER FEEDING OF CHILDREN.

SIR JOHN GORST, M.P., opening the meeting of the Childhood Society to discuss a paper read by Dr. Macnamara, M.P., said the question of the proper feeding of children was important to the future greatness of Great Britain as a world power. As the law compelled children to be sent to school it should see they were in a fit condition to receive instruction.

Dr. MACNAMARA, M.P., then read his paper on the subject. After thirty years' practical experience as teacher and member of the London School Board he had come to two conclusions—(1) that 80 per cent. of the children were better off now than ever; this improvement was due to compulsory education, physical training, and the influence of this on home life; (2) That the remaining 20 per cent. were in an almost hopeless condition. Food, clothing, and housing were bad. Especially was the food unsuitable and insufficient, not only in big cities but in agricultural districts. The London School Board had had several meetings on the subject, and at a special meeting in 1898 concluded that it should no longer be left to charitable relief but ought to be a public obligation. Also that where parents neglected their children through drunkenness or idleness, the Board should have power to prosecute them. Dr. Macnamara considered this last clause very important and regretted that it was rejected finally by the Board. He suggested remedies for the evil which was crippling so many, mentally and physically, and explained a scheme already working in Paris that strengthened instead of weakened parental responsibility. This scheme was:—That dining-rooms should be connected with each school, and parents be invited to buy coupon tickets for wholesome and substantial meals served in these rooms. Gratis tickets to be given to those who could not pay for them, after inquiry. All coupons to be printed precisely the same way, the money for gratis coupons to be recovered if possible by the officers of the Board or deducted from the parents' wages. He thought many parents of the well-to-do artisan class would find it convenient and economical to avail themselves of this communal system. A halfpenny rate for feeding children would finally cost the ratepayers less, as the number of healthy wage-earners would be increased. A system of medical inspection would also improve the condition of the school-children. Evening classes of cooking, hygiene, and domestic economy for young women would be of great advantage. All boys between 14 and 20 should be compelled to give two evenings a week to training, under State auspices, which would include gymnastics, formations of companies and drill, and use of rifles. He strongly urged this, although it sounded like conscription; and also drastic changes in the present state.

Dr. CARR, chief officer of the L.C.C., thought the reports of underfeeding were often exaggerated. He did not approve of the coupon system, as it was open to so much abuse; the wisest thing was to take the child away from parents who could not feed it. Hygiene was more important than some subjects now taught in the schools.

SIR JOHN GORST, in moving a vote of thanks to Dr. Macnamara, insisted that children ought to be protected by law from the neglect of parents, though at present, short of employing the criminal law, it was not possible to do so.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 6th, 1904.

## BLOOD-LETTING IN ECLAMPSIA.

THE treatment of eclampsia, says M. Macé, has undergone important modifications in modern times. Among the means employed against it there is one which had by turns the favour and the reprobation of medical men, *viz.*, blood-letting. "For my part," said M. Depaul, "I do not hesitate to declare that the success obtained I owed to blood-letting. I am one of those who are the warmest partisans of this method of treatment. After having employed in very numerous cases the different methods of treatment recommended against eclampsia myself, I do not hesitate to place blood-letting in the first rank." Since then, the partisans of bleeding at the Maternité of Paris are Dr. Porak and myself, and we find in this method considerable advantages.

Blood-letting is beneficial, and frequently the medical attendant will congratulate himself on having employed it, if he has done so largely, sometimes repeating it on the same patient.

The eclamptic patient suffers from poison of all the organs by the retention in the maternal organism of toxic products which determine disorders in the functions of all the cells, provoking convulsive seizures, either from the condition of the blood or from œdema existing in the nerve centres. The œdema of the cellular tissue is frequently manifest in the extremities, but clinical experience has shown that this œdema can, in certain affections, be localised in the bulb, &c., and produce very grave accidents.

Eclampsia, which announces itself by convulsive attacks—a terrifying and visible symptom—furnishes to the medical attendant a certain number of other symptoms which are also important, arterial hypertension, for instance. Hence, congestion of the kidneys, the possibility of the rupture of a small vessel under the influence of high pressure, and, unfortunately, among the arteries which yield the most frequently are those of the nerve centres. Such, in a few words, are sufficient considerations to indicate the necessity of blood-letting.

Peter recommended it against the renal congestion, which he considered the only cause of eclampsia. Playfair reserved it for cases where there were evident signs of cerebral congestion with vascular tension, lividity of the face, bounding pulse and strong pulsations of the carotids.

Professor Bouchard proved by experiments that in eclampsia the drawing of twelve ounces of blood eliminated one drachm of poison, and to arrive at the same result by purging the patient, diarrhoea bordering on cholera should be provoked, which would thus compromise the life of the patient.

At the Maternité we bled all eclamptic patients systematically as soon as they arrive, without regard to symptoms, and we bleed largely. The least amount drawn was twenty-five ounces, sometimes renewed in the same day. By this means we remove a certain quantity of poison, poison whose nature is not yet well defined, but whose constant presence is the cause of the accidents.

The results of blood-letting might be mentioned as follows:—decrease of the toxic elements of the blood, decrease of the vascular pressure, decrease of the symptoms of asphyxia, decrease of œdema.

## HÆMOPHTYSIS IN PHTHISIS.

Chloride of calcium, drs. j ;

Syrup of opium, oz. j ;

Water, oz. v.

A tablespoonful every two hours ; or  
Hydrochlorate of hydrastinin, gr. ij ;  
Water, oz. v.

A dessert-spoonful every half-hour ; or  
Hydrochlorate of hydrastinin, gr. x ;  
Water, oz. iiss.

For subcutaneous injection. A full syringe (1 gr.) once or twice in the twenty-four hours ; or

Hip. powder, gr. j ;

Dover's powder, gr. ij.

For one wafer : One every hour until nausea sets in.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 6th, 1904.

## ALCOHOL AS A FOOD.

HR. ROSEMANN has an article on this subject in Pfüger's *Archiv*, Bd. 100, which, considering the amount of attention that is being at present bestowed on the alcohol question in Germany, is of interest. According to the writer, the views of the unconditional opponents of alcohol with regard to the question of its nutritive value are not in accordance with actuality.

Of the quantity of alcohol introduced into the system, a little over 2 per cent. leaves the body unconsumed. The elasticity given assists the bodily functions, and limits the consumption of other food material introduced. The albumen-sparing action is not noticeable during the first few days of its use, but later on it becomes evident as in the case of carbohydrates and fats. The interesting fact of the absence of albumen-sparing property during the first few days of its use cannot be explained by its washing out remaining terminal products of tissue change. Rosemann sums up the results of all experiments on the subject to the effect that alcohol in regard to its action as a food stands exactly on the line of carbohydrates and fats.

As regards its poisonous action in large doses, he does not believe that moderate doses of alcohol have any poisonous action. For the determination of this question, however, no material is at hand, and it would be difficult to procure it. Bismarck and Goethe would scarcely have done more, or lived longer, if they had been total abstainers.

In any case, the use of alcohol as a food to the healthy individual is not in any way prejudiced by any supposed poisonous by-effects. He would in no way minimise its practical and most valuable action as a food.

## INTESTINAL ANTISEPTIS.

In a discussion on this subject (Merck's *Archiv*), Dr. Soln Cohen made a suggestion that may lead to useful results. Everyone knows the difficulty there is in isolating and capturing any specific bacillus that may be causing mischief in the intestinal canal, and valuable time may easily be lost in making such bacteriological investigations as shall identify the offender. In order to shorten the way out of this difficulty he suggests the use of combined intestinal antiseptics, guaiacol carbonate (duotal), benzo-naphthol and bismuth salicylate. By this combined method he believes that the septic action of many groups of bacteria will be materially limited.

## THE GENESIS OF PULMONARY PHTHISIS.

A discussion on this subject took place at the Naturforscherversammlung, introduced by Hr. Aurfrecht, of Magdeburg. He had never observed that phthisis began by inspiration into the healthy lung. The diseased walls of the blood-vessels caused the caseous tubercle of the human subject. The tubercle bacilli forced themselves into the blood-vessels, possibly through the tonsils, the glands of the neck, and mediastinum.

Petruschky laid the commencement of phthisis in childhood ; scrofulous glands indicated it. Timely and efficient tuberculin treatment gave a prospect of recovery.

Wassermann held tubercle in the veins to be accidental. In a case in his own practice the cervical glands were first diseased and later on pulmonary consumption set in.

Lugenbuhl did not understand what Petruschky meant, and the latter explained that tuberculous women might get over their confinements without

danger, and that prophylactic treatment of young children with tuberculin might enable them to avoid grave tuberculosis in their offspring.

In the Section for Gynaecology, Hr. Schenck described his

#### COMPARATIVE EXAMINATION OF BLOOD.

He could prove that the resorption of tissue elements during involution of the uterus played a part. He was also able to recognise a distinction between the streptococci of the normal lochia and the streptococcus pyogenes. The difference was morphological, and also in staining characteristics and culture. Polano, Würzburg, found, contrary to the general assumption, that in the human subject the antitoxin passed from the mother to the foetus through the placenta, and that this was the case in both active and passive immunisation. Living cells were not bound by simple physical laws, and he instanced the varied composition of the chemical elements of the protoplasm in the different parts of the body.

#### VERONAL POISONING.

Three cases are reported by Dr. P. A. Fenger Just (*Deutsch. med. Zeit.*, Bd. 83, 1904). The first was that of a woman, æt. 25, who for sleeplessness had taken various hypnotics without any special result. She took then, in the evening,  $7\frac{1}{2}$  grains of veronal for a week together, with eight hours' restful sleep. After the ninth dose she had a heat and such itching about the ears, arms, and legs that she could not stay in bed. There was thirst, and then a rash of confluent reddish-violet spots all over the body, which disappeared in ten days.

Case 2 was also one of a neurasthenic single woman, æt. 28. A dose of  $7\frac{1}{2}$  grains of veronal for six nights in succession acted well, but the seventh was followed by symptoms similar to those described in the preceding case.

The third case was that of a woman, æt. 52, who had had an abscess opened in the right hypochondrium, from which a large quantity of stinking pus was evacuated. Being sleepless, she was given  $7\frac{1}{2}$  grains of veronal every evening for five evenings; then for two evenings  $3\frac{1}{2}$  grains were given, and after the second the same itching and rash appeared. In three days it was gone.

VIENNA, November 5th, 1904.

#### HEPATIC CIRRHOSIS.

At the Naturforscher meeting, Kretz gave an exhaustive description of the various causes of hepatic cirrhosis which may be concisely stated in the shape of a few axioms:—

1. Interstitial hepatitis does not produce granular cirrhosis of the liver, but parenchymatous changes from repeated attacks and recovery lead to degenerative cirrhosis.

2. The elastic fibres gradually disappear from the fibrous tissue of the organ, leaving the vessels supported by the hard degenerated paenchyma of the organ. The arterial portion of the liver is not the first portion to be attacked but is gradually invaded from the parenchymatous centre.

3. In his third section he laboured the question of hepatic cirrhosis being a morbid entity, or, in other words, having a specific virus. He contended that it was not, as it depended upon cell degeneration for its origin; these degenerated cells localised themselves, forming a neoplasm, which finally invaded the whole organ, subsequently displacing the whole of the healthy tissue.

The etiology of the disease depended on all the causes that produced degenerative changes in the parenchyma, such as poisons, imperfect metabolism, bacterial action, &c. There is also another source of injury to the hepatic cells through the hæmatic circulation or the capillaries of the gall-ducts.

Naunyn thought these different forms of cirrhosis could not be diagnosed with any hope of accuracy, although for classification pathologically he would willingly arrange them as incipient cirrhosis, atrophic or ascetic cirrhosis, biliary or hypertrophic cirrhosis, and Eantic or hypersplenic cirrhosis. These different forms of cirrhosis do not depend upon the different causes of the morbid process, but rather on the complications of cirrhotic cholangitis, which may be considered an intestinal ascending cholangitis, which is not the direct cause of the disease but a factor leading to the morbid process. The differential diagnosis of intestinal and splenic cirrhosis is not clearly established, although the hæmogenic form is conceivable and logical. In the latter case hæmolysis plays an active part in the cirrhotic cholangitis, which may be termed descending cholangiolitis.

The symptoms of this disease are sometimes obscure, owing to the variety of disturbances affecting the function of the liver. Alimentary levuloseuria is a doubtful condition as we do not yet know exactly whether the sugar is directly taken from the blood. The diagnosis of cirrhosis depends chiefly on the anatomical changes. Leichtenstein was the first to announce that cirrhosis of the liver was preceded by enlargement of the spleen, and that cirrhosis of the liver never preceded this condition, but later investigation has proved that the early stage of the disease has the hardened condition of the liver as early as it can be distinguished in the spleen. Banti's cirrhosis has nothing specific to distinguish it, as the large spleen, anæmia and hæmorrhagic diathesis are common to all the forms of the disease, although age may be suspected as an important factor in the development of the hypersplenic form, which has strangely been called pseudo-Banti's disease, apparently depending upon a toxæmic albuminoid which is cured by extirpation of the spleen. Closer inspection of the anatomy shows that this form of cirrhosis is not the genuine hepatic hardening, but only an increased growth of the hepatic cells in the acini. This condition, he affirmed, often took place in cases of lithiasis or after hepatic colic. He was inclined to believe in the cause being an infectious inflammation of the gall-duct as cholangitis cirrhotica was a frequent and important complication in the symptoms commencing with fever, vomiting, and icterus. He could not accept cholangitis ascendens as a cause of cirrhosis as the transformation of cholelithiasis into cirrhosis has never been observed. In his opinion the etiology of cirrhosis was alcohol, which may sometimes be associated with lues, typhoid, and the puerperium. The changes observed in the bowel and spleen by Bleichröder are not specific symptoms, but are common to all hepatic changes. Neither can the blood be used for diagnostic purposes as no specific blood change can be defined, yet we are unable to deny the possibility of a hæmatogenic origin as the toxin may pass from the bowel into the hæmatic circulation and produce irreparable damage to the follicles of the corpuscle, which may be one explanation for Kretz regularly finding "hæmachromatose" in the liver. It is common knowledge, however, that alcohol injures the erythrocytes of the blood and retains them in the liver till they become destroyed, leaving the *débris* in the organ as a centre of destruction.

Aufrecht wished it to be clearly understood that interstitial inflammation did not exist in cirrhosis, but only an apparent increase of the fibrous tissue owing to the solution of the acini, which gave the section of a cirrhotic liver a smooth appearance. He gave it as his opinion that the initial stage of cirrhosis could not be diagnosed as many simple enlargements disappear quite easily without any evil consequences, although others may end in acute atrophy and become decidedly cirrhotic.

Chiari directed the attention of the members to the enormous growth of the parenchyma in cirrhotic conditions. It was never constant in quantity, but varied considerably as clinical differences went to prove. In addition to this there was often a secondary inter-

stitial process. He related a number of cases that ended fatally in necrosis.

Bebes showed a photograph of a primary parenchymatous centre, which partially passed through secondary degeneration.

Bleichröder related the results of his histological examination of the stomach, bowel, spleen, and marrow in hepatic cirrhosis, which, he said, resembled pernicious anæmia in every detail.

Frey-mouth said that he once diagnosed a case of incipient cirrhosis after having performed laparotomy for a neoplasm in the liver!

Steinberg disagreed with Bleichröder's conclusions as the breaking down of the lymphocytes in the blood-vessels or the changes in the fibrous cells could not be shown.

Hanse-mann said that he had seen two cases of cirrhosis that had arisen from inflammation of the gall-ducts. He was not a believer in the alcoholic etiology of cirrhosis because many men and women drank to excess and no cirrhosis ever occurred.

## Bungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, November 5th, 1904.

At the October meeting of the Interhospital Medical Association, held here, Dr. T. Gáspár introduced the subject of

### EARLY DIAGNOSIS IN MENTAL DISEASES.

He defined insanity, according to Burr, as a "prolonged departure from the individual's normal standard of thinking, feeling, and acting." A comprehensive definition would include mental defect from whatever cause, and mental perturbation of whatever degree. Any or all of the elemental processes of sensation, perception, ideation, reasoning, judgment, memory, may be impaired in insanity. In his paper, the nature and degree of impairment of these elemental processes and of emotion and volition in different forms of insanity, were touched upon. Subjects discussed at greater length were the distinction between confirmed inebriety and true insanity of alcoholic origin; the differential diagnosis of alcoholic pseudoparesis and parietic dementia; certain phases of hysteria, and the diagnostic difficulties pertaining to paranoia and recurrent mania. Neurasthenia was a euphemism often employed to obviate the necessity of plain speaking, or might be used erroneously to explain symptoms in the early stages of an organic malady. The self-deception on the part of the physician or his inaccuracy in diagnosis led to improper methods of management, and the prescription of travel often made for such patients was deplored and incidentally hospital care for neurasthenic cases was advised.

Dr. Makkay delivered an address on the  
PREVENTION OF HEART DISEASES.

He discussed in what manner the principles of prevention could be applied to various heart affections. He regarded the removal of all chronically diseased tonsils (this was first recommended by Dr. R. Babcock, of Chicago) as of the utmost importance in all persons who had once had an attack of inflammatory rheumatism, whether the heart had been damaged or not. If infection could be prevented, cardiac inflammation could likewise be obviated. This statement applied to other affections than rheumatism. He then mentioned syphilis and gonorrhœa, saying that these diseases sometimes attacked the cardiac structures. Pneumonia, chorea, scarlatina, are sometimes accompanied or followed by acute or chronic endocardial mischief, while influenza or diphtheria may attack the myocardium in an inflammatory way, so as to seriously impair its integrity. Until we could prevent such infections, we could not guard against the cardiac structures being attacked. The author discussed chronic myocardial diseases, the toxic influence of syphilis, alcohol, and chronic lead poisoning, fatty heart, and particularly cardiac overstrain, as it is

observed in the young, and sometimes in the middle-aged, and apparently healthy, as the result of excessive physical exertion, and mentioned typical examples of this kind.

### HEREDITARY SYPHILIS.

Dr. Tustus has said that the symptoms of hereditary syphilis are generally manifest at birth, or appear within the first two or three months. They are the same as in the acquired disease of adults, but differ in their sequence, and in the regularity of their appearance. In tardy hereditary syphilis, tertiary signs may make their appearance as late as the twentieth year. He divides these cases into two classes, *viz.*, where syphilitic manifestations were present in earliest youth and had disappeared with proper treatment; and, secondly, where these late signs gave the first suspicion of infection. This class is not recognised by many syphilographers; however, two undoubted cases were described by Continental authors. It generally appears as a bilateral affection of the knees, either an arthralgia, a simple chronic hydrops, a syphilitic tumour albus, or a deforming arthritis. It is often extremely difficult to diagnose, but if no direct history is present, anti-syphilitic treatment should be resorted to in all symmetrical cases, which resist other measures, especially if there are marked fluctuations in the course. Often the presence of a parenchymatous keratitis will assist diagnosis.

## The Operating Theatres.

### ST. THOMAS'S HOSPITAL.

OPERATION FOR PERFORATED GASTRIC ULCER.—Mr. BATTLE operated on a man, *æt.* 52, who had been under the care of his colleague, Dr. Hector Mackenzie. The patient had been complaining of stomach symptoms for two or three years, and had been admitted under the care of Dr. Mackenzie for an increase of these symptoms, which led to the diagnosis of simple ulcer of the stomach situated near the pyloric extremity associated with dilatation of that organ. The man complained of a good deal of epigastric pain and of vomiting, the quantity of material brought up being rather large, and three days before operation he had been put on rectal feeding, because his pain had been so severe. At ten o'clock on the previous night he had complained of increase in the pain, and had become much worse. When seen shortly before operation he was lying on his back, with a pale face and distressed expression, breathing rapidly, but not employing his diaphragm or abdominal muscles more than was absolutely necessary. He had much abdominal pain, chiefly in the upper part of the abdomen. On examination, the latter was found to be slightly distended, rigid and without movement on respiration. It was tender on pressure, and there was evidence of considerable fluid throughout, both in the flanks and above the pubes. The liver dulness was not lost, nor was there evidence of free gas in the peritoneum. Operation was performed about eighteen hours after the time of the probable perforation. A median incision was first made in the epigastric region; on opening the peritoneum a large quantity of sour-smelling greenish fluid escaped. The omentum and lower margin of the stomach were attached to the under surface of the liver by means of recent exudation, but these attachments separated directly the finger encountered them as it was passed towards the pyloric end of the stomach in search of the perforation or of evidence of chronic thickening. At this point there was an escape of free

gas. The finger readily located the ulcer, the opening being so large that the end of the finger could be easily passed through it into the stomach; its margin was very sharply cut, and the area of induration extended for about an inch and a half around it. The stomach was dilated. The pyloric end was drawn forward and held in position by Mr. Birks, the house surgeon, whilst sutures were inserted. On account of the size of the ulcer two sutures were passed to approximate the edges of the perforation; then a row after Lembert's method to cover it over completely, and finally an additional suture to take off some of the tension, which seemed to try some of the second row of stitches. The silk employed was No. 2, because it was found that smaller sizes than this cut their way out at once. Another opening was made in the middle line above the pubes and the whole peritoneal cavity thoroughly cleansed with warm saline solution until the liquid no longer had any colour or sour smell. The fluid which had escaped in the first instance from the perforation must have amounted to several pints, as it filled the pelvis and the flanks, and had collected to a large amount in the splenic region and about the right lobe of the liver. The upper wound was closed in three layers by means of interrupted sutures, whilst a drainage-tube was left in the pelvis, coming out through the lower wound. Towards the end of the operation the patient's pulse failed somewhat and he began to show signs of collapse; an infusion into the left arm of two pints of normal saline improved his condition rapidly, and he soon recovered. Mr. Battle pointed out that the ulcer had been found in the position where the physician had diagnosed its presence, and the other conditions were as expected; the only unusual thing about the case, he thought, was the large size of the opening into the stomach and its extremely sharp-cut cicatricial edges. The diagnosis even in the absence of proof of free gas, he said, was quite easy, and the patient was already in an exceptionally good condition as the result of nearly three days' treatment by rectal feeding. The ulcer, together with the inflammatory swelling round it, did not appear to actually obstruct the pylorus, but was close to it, and there was no doubt that obstruction had been present, as was shown by the dilated condition of the stomach, for which he thought it might possibly be necessary to do a gastro-enterostomy at a later date.

The operation relieved the man at once, his pain being completely gone when he recovered consciousness, and since that time he has progressed most favourably.

#### GREAT NORTHERN HOSPITAL.

##### SUPRAPUBIC CYSTOTOMY.— HOUR-GLASS BLADDER.

—Mr. PEYTON BEALE operated on a man, æt. 54, whose history was as follows: He was a shunter in the employ of the Great Northern Railway, and had been able to work until about six months ago, when he complained of pain in the left loin extending to the abdomen and to the left leg; he also passed some blood with his urine, and was treated by a doctor for stone in the left kidney. He was sent to the hospital by Dr. G. R. Williams. On examination under an anæsthetic a sound was passed into the bladder as a routine process, and after some slight obstruction had been encountered about the membranous urethra a stone was easily felt lying at the base of the bladder, not encysted; one or more smaller stones were also to be felt. It was

noticed that the capacity of the bladder was small, and it was known that the man had increased frequency of micturition and passed only three or four ounces of urine at a time; but these being not unusual symptoms in connection with stone or stones in the bladder, nothing much was thought of them. On abdominal palpation there was nothing to indicate any derangement of the left kidney. As there had clearly been some old urethral trouble whereby the urethra would only now admit a No. 6 instrument, it was thought advisable to perform suprapubic cystotomy in preference to a perineal operation. A few days later, therefore, suprapubic cystotomy was performed, a Lister's sound having been introduced into the bladder and the stone again detected. The bladder was easily reached and at once recognised; but in a higher position than was expected from its apparent size at the first sounding. The bladder was opened and was found to contain no urine, nor could the sound and stone be detected in it. On further examination the instrument and stone could just be reached by the tip of the forefinger very deep down in the pelvis. It was then evident that this latter was the functional bladder, and that the large cavity above was completely shut off from it. It should be remembered, Mr. Beale now pointed out, that previous attempts at distending the bladder by fluid injections had been quite unsuccessful. As the portion of bladder containing the sound and stone could not be reached through the suprapubic wound sufficiently to enable the stone to be satisfactorily dealt with, the upper part of the bladder was stitched up and the abdominal wound closed in the usual way. Mr. Beale said that the case was interesting for two reasons: First, because all the man's symptoms pointed to a derangement of the left kidney. In all urinary cases he considered it advisable always to examine the patient under an anæsthetic and explore the bladder at the same time, because it was a very noticeable fact that a stone might exist in the bladder for a long period without giving rise to classical symptoms. Secondly, the hour-glass contraction was of interest; such cases, he thought, were very difficult to deal with, for when the stone was lying in a small bladder lithotripsy was not desirable even if the urethra was normal. By suprapubic cystotomy it was often, as in this case, he said, not possible to remove the stone satisfactorily; and in his experience if perineal section or lithotomy were performed a permanent fistula was a very common complication, due apparently to the fact that the small bladder continually expelled the urine as it entered it and allowed little if any of the fluid to accumulate in it.

#### The Royal University of Ireland.

At a meeting of the Senate, on Thursday, October 27th, the results of the recent examinations were received and Honours exhibitions and prizes awarded. It was resolved that, subject to certain restrictions, the books in the University library and the University grounds should be made available for graduates of the University during portions of the year.

The following have received the M.D. Degree:—George Adams Hicks, M.B., B.Ch., B.A.O., Daniel Lee, M.B., M.Ch., M.A.O., John Elder MacIlwaine, M.B., B.Ch., B.A.O., Michael Joseph Mahony, M.B., B.Ch., B.A.O., John Hope Reford, B.A., M.B., B.Ch., B.A.O., John Stewart Ferguson Weir, M.B., B.Ch., B.A.O.

WEDNESDAY, NOVEMBER 9, 1904.

**THE SMALL HOSPITALS AND THE FUNDS.**

THE smaller hospitals of the Metropolis, and to a less extent of the provinces, have during recent years been faced with increased difficulties in maintaining their existence. The struggle has been no doubt partly due to the scarcity of money which has resulted from depressed trade and depleted national wealth. Another cause has been the diversion of huge sums of money in answer to appeals issued to the public by the great general hospitals one after the other, in some cases to be repeated after a few years' interval. The chief cause of the decline of the small hospitals, however, has in all probability been the policy of the Sunday and the King Edward's Hospital Funds, which, whether intentionally or otherwise, has resulted in the withholding of grants and injury to the reputation of a host of small but deserving medical charities. The relation of the lesser hospitals to the Funds is peculiar. When the Funds were started as collecting and distributing agencies, the small hospitals sacrificed the income derived from special collections in places of worship. They next lost the support of many subscribers who withdrew or refused subscriptions on the ground that they contributed to the Funds. Finally, the Hospital Sunday and the King Edward's Hospital Fund have in many cases refused grants to small hospitals. It will be seen, therefore, that in this case the poor hospital has lost much and gained nothing. Furthermore, the refusal by a Fund of a grant to any particular hospital is looked upon by the general public as a slur upon the character of that institution. So that loss of character as well as of income is the inevitable

fate of the small hospitals under the Fund methods of distribution of alms. In other words, the days of the small hospital are numbered under the control of the Funds. We venture to assert that this result is due to the deliberate policy of those who administer these, and was never contemplated by the public whose money had previously been given freely to the medical charities, great and small. It is necessary here to state clearly that the Hospital Saturday Fund supports loyally and consistently the smaller hospitals. The Saturday Fund is controlled mainly by representatives from the hospitals and from the classes who are benefited by the hospitals, and they are accordingly from that point of view peculiarly fitted to judge what charities do and do not deserve support. We find the Saturday Fund extending the hand of practical sympathy and help to the smaller hospitals, whereas the sister Funds have to a great extent taken away both income and character. Which is right, the Hospital Saturday on the one hand, or the Hospital Sunday and the King Edward's Funds on the other? The administration of all these Funds is, happily, in the hands of honourable men; but while that of the Saturday Fund, as already pointed out, is democratic, that of the other two may be termed aristocratic and even autocratic. The latter term may sound harsh, but it is not easy to find any adequate alternative to express the policy of a Fund that deprives small hospitals both of income and of character without clearly stating the principles, general and particular, upon which their action is based. The principles of the Hospital Sunday and the King Edward's Funds cannot be gauged from ordinary observation and reasoning. If there be one principle paramount in those Funds it is the advocacy of payments by hospital patients. If the principle be right, it follows that the hospital which receives the greater part of its costs of treatment from patients is the better hospital. Yet the Funds deny grants to institutions where patients' payments exceed a certain proportion of income. The economy with which a hospital is managed and the smallness or absence of debt appear not to influence grants except perhaps in inverse proportion. Why should not the small hospitals and the poorer classes be adequately represented on the Hospital Sunday and the King Edward's Funds as they are on the Hospital Saturday Fund? Far be it from us to say one word against the good faith and the immaculate honour of both those Funds. They are public bodies, however, and are therefore open to criticism. We are no less willing to praise their virtues than we are ready to criticise their defects. The faults, we believe, may readily be remedied. Our great and wise King, who created one of these bodies, may with a stroke of the pen revise the constitution of his Hospital Fund, so as to make it more generally representative of all classes, and at the same time remove what, in our opinion, constitutes a grave injustice to the small

hospitals, which are in many instances carefully administered, ably officered and old-established institutions, invaluable alike to the public and to the medical profession.

#### THE VITAL STATISTICS OF IRELAND.

THE fortieth report of the Registrar-General for Ireland, which has recently been issued, does not show any new factor influencing the population, which continues to decrease in practically the same proportion as during the past ten years. The total number of births last year, presenting precisely the same rate per thousand of the population as the average for the past ten years, was 101,831, exceeding the number of deaths by 24,473. This shows a fair natural increase in the population, but, unfortunately, it is more than counterbalanced by the loss through emigration, amounting to 39,789. It will be seen that the decreasing population is not due to any vital causes, but to economic and, as some hold, to sentimental ones. There is little doubt that the economic position of Ireland is, during the last few years, improving, so that it is disappointing that the emigration figures are as high as ever. Trade in both large and small towns is livelier than in the eighties, agriculture is conducted by more intelligent methods, and the settlement of the land question gives the occupier an interest in his toil he never had before. Nevertheless, the steady drain of the best blood of Ireland continues from Derry in the North as from Queenstown in the South. It is truly an appalling fact that every year the loss by emigration is more than half that by death. Under the circumstances it is matter for surprise that the death-rate is so moderate as we find it—last year  $17\frac{1}{2}$  per thousand—since it is the young and strong who go, and the old and infirm who stay. Melancholy reading as is the Report as a whole, there are yet some points of relief. The vitality of the people is by no means low, as evidenced by the high birth-rate taken in proportion to the marriage-rate, and it is probably some evidence of prosperity that the latter shows during the past few years a steady increase. The number of persons married as minors is very small—of men, 1.57 per cent., of women, 6.50—and is in marked contrast to the numbers noted in industrial populations. The rate of illegitimate births shows a similar contrast. The percentage of children born outside wedlock is only 2.6, varying from 0.5 in the agricultural population of Connaught to 3.3 in partially industrial Ulster. A point of interest in the list of certified causes of death, showing, too, the remarkable vitality of the Irish people, is the number of deaths returned as due to "old age," many of them at ages exceeding ninety-five years, and 176 at ages over one hundred. "Old age," indeed, is made accountable for the highest number of deaths, with the exception of tuberculosis. While in England and Scotland the mortality due to tuberculosis has steadily dimin-

ished during the past thirty years, in Ireland it has remained stationary, with, in late years, a slight tendency to rise. The problem of the check of consumption is one of the utmost public importance. Public men are busy in schemes to lessen Irish emigration, and we wish them every success, but we think that enough attention is not given to the more easily preventable loss of population by tuberculous disease. A few, but only a few, boards of guardians are awake to its real importance, though the medical profession does its best to call attention to the matter. The death-rate from cancer continues to increase in Ireland, having reached its highest point last year. We think, however, that the Registrar-General is right when he points out that the increase is more apparent than real, since diagnosis and classification are becoming more accurate. The zymotic death-rate is, as one would expect, low, influenza being the most important zymotic disease tabulated.

#### MILK-BORNE DISEASE.

A CASE of the greatest interest to milk-consumers—that is to say, to the whole British public—came last week before the courts of justice. The facts disclosed were that a lady was taken ill in July, 1903, with typhoid fever, and eventually died. In the district in which she lived there were at or about the same time twenty-one cases of the disease, and twelve of these patients drew their milk supply from one dairy. The medical officer of health made inquiries and he came to the conclusion that the source of the outbreak—at any rate, as regarded the latter twelve cases—was due to the milk they had been drinking. The lady's husband brought an action against the dairy company for the loss he had sustained by reason of the death of his wife and for the out-of-pocket expenses he had incurred through her illness. In evidence it was stated that a case of typhoid fever had occurred in a cottage connected with one of the farms whence the company drew their milk, and it was contended by the plaintiffs and denied by the defendants that there was sufficient evidence to connect this case with the outbreak among the consumers. The plaintiff's counsel relied not only on the general principle that a purveyor is bound to supply food that is not injurious to health, but also on the special statement in the company's advertisements that they were in a position to guarantee their milk to be free from disease germs. Mr. Lawson Walton, for the defence, submitted that the evidence was not sufficient to support the plaintiff's contention, but the judge (Mr. Justice Grantham) held that the case was one of fact and must be decided by the jury. Witnesses were called on both sides to prove whether or no the case of typhoid at the farm had any etiological relation to the cases amongst the consumers, and eventually the jury decided for the plaintiff, only awarding him, however, £106, the amount at which they assessed his out-of-pocket expenses. Judgment

was therefore given for that amount with costs. In some ways it is unfortunate that the particular company against whom this verdict was given should have been the first to suffer in an action of the kind, for they are known to take elaborate precaution to guard their milk from contamination, and it appears to have been through a breach of their stringent rules that the milk from this farm ever got into the general supply. Moreover, when suspicion was aroused and the circumstances were brought to light, the milk from the particular farm was at once withdrawn. There will always be a possibility of flaws in the best organisations, and in this case the company had to suffer from a fault that could only be indirectly attributed to them—that is, assuming that the case of typhoid at the farm was really the cause of the outbreak. As to this, although the jury held that it was the cause, there was a good deal of conflicting evidence, and indeed, in the present state of medical knowledge it is seldom possible to establish an irrefutable chain of evidence in circumstances of the kind. However hardly in this instance the jury's verdict may press on the company, we are inclined to see in the principle of this action a method for solving the problem of the present highly unsatisfactory state of the milk trade generally. It has now been held by a judge, and confirmed by a jury, that the sale of milk carries with it an implied warranty as to its wholesomeness, and that in the event of damage resulting to the consumer an action for damages will lie against the vendor. In the event of disease arising from any contamination of milk, any and every person injured thereby will have a *prima facie* case against the purveyor; and the recognition of this liability by the trade cannot, one would think, but tend to make them take their responsibilities far more seriously. As we have more than once pointed out, the difficulty in setting this important trade into satisfactory order lies in the multiplicity of hands through which the milk passes before it finds its way into the domestic jug, and, where responsibility is divided, it is notoriously hard to fix blame. Now that it has been held that the vendor is the responsible party, he will probably take every care to see that he is not let in for expense and damage by those from whom he draws supplies, and thus the whole array of agents who have to do with the supplies of milk—farmers, servants, railway companies, and collectors—will be made aware of their duties and responsibilities to the purveyor and, through him, to the public. Our remarks do not apply with any particular force to any particular dairy company, but to the whole of those persons handling milk who intervene between the cow and the consumer. It is astonishing to compare the energy with which municipal authorities pounce on dairymen who water their milk with the complaisance of those authorities towards vendors who sell milk that is stale, dirty, and perhaps infected with disease. But what legislation and administration have failed to do, what a sanitary department and a standing army

of inspectors have been powerless to touch, now appears likely to be accomplished in the near future if we are to take this verdict as representing the feeling of the public. Milk, which is only preserved from going sour by the addition of boric acid or formalin, and which contains sufficient bacterial products to give diarrhoea to many a score of babies, may now get the vendor into trouble through the most effective channel—namely the pocket. In acclaiming the verdict as a miniature Magna Charta to the milk-drinking public, we are only sorry that the blow fell in the particular direction where it did.

### Notes on Current Topics.

#### Direct Bronchoscopy.

A GREAT deal of the progress in medicine depends on the progress made by the other arts and sciences, and medical diagnosis and surgical treatment has been immensely facilitated by the inventive genius of a few men who have been able to place instruments of precision in the hands of medical men. The laryngoscope and ophthalmoscope are now everyday implements with most practitioners, and several other "scopes" are daily coming to be regarded as an essential part of the consulting-room furniture. Few, however, are yet practised with the bronchoscope, and still fewer have had the opportunity of operating with its aid. Indeed, a great deal of scepticism has been expressed as to the practical utility of the invention. Two German surgeons, Nehr Korn and Killiau, have lately been describing their manipulations with its aid, and in their hands it appears to have been highly useful. Killiau reports his sixteenth case of removal of a foreign body from the bronchi by the assistance of the bronchoscope, and Nehr Korn describes three similar cases that were under his care. The former was consulted by a man aged fifty-six, who had inhaled a piece of chicken bone whilst drinking a plateful of soup two months previously. Convulsive choking followed the passage of the bone into the air-passages, and though this gradually passed off the patient continued to have noisy dyspnoea. The foreign body remained and could not be removed by the surgeons he consulted. Physical signs in the chest pointed to the left bronchus being partly occluded, and the mucous membrane of that tube was seen by the bronchoscope to be reddened. Killiau operated under an anaesthetic, passing the instrument well down into the bronchus, and by its aid he was able to seize the bone with long forceps. When withdrawn the bone was covered with foetid pus, but the patient made a good recovery. Nehr Korn's three patients were all children in whom beans had become lodged in the bronchus, and though he managed by the aid of the bronchoscope to remove these foreign bodies in two cases, in a third he had to perform tracheotomy and pass the instrument through the wound. All recovered satisfactorily. To use the bronchoscope skilfully requires some little practice, but

it should certainly prove a great help in those difficult and dangerous cases of obstruction of the bronchi by foreign substances for which so far surgery has been able to do but little.

#### Surgical Treatment in Gout.

THE medical treatment of podagra is not altogether satisfactory; neither is the surgical treatment. The swollen big-toe joint with its traditional associations of port wine and bad temper, has always been regarded as one of the special preserves of the physician; but nothing is sacred nowadays from the operating surgeon, and one cannot be astonished that he has now turned his attention to the gouty joint. The first occasion was accidental, or rather the result of mistaken diagnosis. Riedal (*a*) was called to see a middle-aged gentleman who, the night following a hard day's shooting, was awakened by severe pain in the right great toe-joint. The joint was much swollen and intensely painful; the skin over it hot and shiny; the body temperature 102° F. Finding that the patient had a condition of hallux valgus, Riedal thought that his trouble was caused by suppuration in a bursa over the metatarsophalangeal articulation which communicated with the interior of the joint. He therefore operated. No bursa was found, and instead of pus the joint was filled with urates and serous fluid under pressure. He decided to continue the operation, and after removing the deposit he took away the capsule of the joint and drained the wound. The patient was entirely free from pain and fever after he came round from the anæsthetic, and never had any further trouble in the toe although he lived for fifteen years afterwards. It was not till twelve years later that Riedal could persuade another patient to allow him to operate for gout, but one old lady was at last found to consent, and he again opened and drained the great toe-joint, after removing the capsule. In her, too, a complete and gratifying recovery followed. No relapse took place for the eight remaining years of her life. One is hardly surprised, therefore, that the surgeon should think that in certain cases of monarticular gout, operative treatment may be as justifiable as it was successful in the two cases recorded. In this country, however, accustomed as people are to the idea of being subjected to the surgeon's knife, we fancy they are not yet prepared to submit their gouty joints to his tender mercies.

#### The Cape as a Health Resort.

FOR many years South Africa has enjoyed, in common with Australia, New Zealand, and Colorado, a high reputation as a health resort for patients suffering from pulmonary phthisis. Recent events, moreover, which have made South Africa appear for the time the land of promise, have directed the attention of many invalids to that country. Under the circumstances, it is important that physicians at home should be in a position to offer advice to their patients who may intend to emigrate, not merely on the subject of the

choice of destination, but as to the necessary conditions of life and probable chance of employment. The most important point to be decided is whether a patient should be advised at all to go abroad. There is no doubt that in many cases a patient, in an advanced stage of phthisis, with cough, expectoration, and pyrexia, will not lengthen his life one day by a change of climate. On the other hand, he merely suffers the misery of his last illness among strangers in a foreign land, away from all the comforts of home and friendship. Still, hope being what it is, one rarely likes to leave untried what may after all be a chance of recovery, and one can recall many cases of recovery even among the apparently hopeless. In going to South Africa, a patient, even in early stages of consumption, must be supplied with sufficient means to keep him for at least a year or two. Otherwise he will probably find his choice of employment limited, and he may be forced into work which will prove disastrous to his health. Great attention must be paid to the choice of residence, the altitude being the most important factor. In the low altitudes in Cape Colony, up to eight hundred feet, there is plentiful vegetation and much moisture, while in the high altitudes of the Great Karroo, two to five thousand feet, conditions are quite opposite. It may, however, be wiser for the physician at home to leave the decision of a suitable locality to a *confrère* at Cape Town, and indeed, a patient should always be warned to lose no time in placing himself under a competent physician on his arrival in a new country.

#### Chloroform Anæsthesia.

IT can hardly be said that the discussion on chloroform anæsthesia which took place at the annual meeting of the British Medical Association has advanced our knowledge of the subject to any appreciable extent. Indeed, there was but little attempt to treat the subject as a whole and most of the discussion centred round Mr. Vernon Harcourt's inhaler. It will be remembered that when this apparatus was first introduced, it was received with such a chorus of praise that one might have been forgiven for imagining that the last word had been said as regarded the method of chloroform administration. It was claimed, not so much by the distinguished inventor as by others, that with this apparatus over-dosage was impossible, and chloroform mortality was to be a thing of the past. Further, the inhaler was so simple in its use that even the most ignorant practitioner could employ it with safety to the patient and comfort to himself. That these exaggerated claims have not been borne out is made abundantly evident by the criticisms to which it has been subjected by competent anæsthetists like Mr. Crouch, of St. Thomas's, and Dr. Levy, of Guy's. It is their experience that not only is it possible for over-dosage to occur, but that unless the chloroform bottle is rigidly secured against shaking there is no guarantee that the percentage of chloroform vapour in the inspired air

(a) *Deut. med. Wochensh.*, August 25th, 1904.

is kept within safe limits. In addition there is the very strong practical objection that the period of induction is extremely long, the average apparently being at least fifteen minutes. As Mr. Crouch remarked, "even the most good-natured surgeon declined to wait the necessary time." On the other hand, Dr. Dudley Buxton has used the apparatus with success in several hundred cases, though, as far as we know, no details of them have yet been made known, and it was more than hinted in the Oxford discussion that there were others in which he had not been so fortunate. Speaking as generally as we can from the evidence at present before us, Mr. Harcourt's inhaler seems a useful invention when in skilled hands, but, like all other chloroform inhalers, requires great care in using, and by no means relieves the anæsthetist of his responsibility in the choice of chloroform as an anæsthetic. We do not, indeed, understand why there has been such a prother as to the best method of administering chloroform. In these countries there is but little necessity for its use at all, seeing that in the great majority of cases it offers no particular advantages over ether, ethyl chloride or gas. When a useful apparatus for administration becomes an inducement to use chloroform for such operations as extractions of teeth, as has actually occurred with the Harcourt inhaler, its introduction may prove an evil rather than a blessing.

#### The Significance of the Diazo Reaction.

THE value of a clinical test becomes obviously impaired when once it is found that there are important and frequent exceptions to its positive reaction. The test discovered by Ehrlich in 1882, known as the "diazo reaction," consists in adding a mixture of sulphanilic and hydrochloric acids containing sodium nitrite to a typhoid urine, when, on alkalisising with ammonia, a cherry-red or garnet ring is produced. This appearance was at first supposed to be distinctive of typhoid fever, but subsequent investigations showed the contrary. Other diseases, such as tuberculosis, scarlet fever and measles, were found to give positive results with Ehrlich's test, so that the hope, which was first entertained, of being able to diagnose enteric fever in the early stages by examination of the urine was not fulfilled. Many observers have since pursued exhaustive investigations upon the subject with results that are not altogether unfruitful. In 1902, the Health Department of New York City undertook the examination of typhoid urines by the diazo reaction, and it was found that this test was more constant even than the Widal reaction. Dr. W. Taylor Cummins, (a) of Pennsylvania, has himself gone over the ground again, having examined 436 urines with regard to their behaviour to the diazo reaction. In typhoid fever, 58.6 of the cases gave positive results, a somewhat smaller proportion than that obtained by most other observers. Dr. Cummins concludes that a relapse

may be differentiated from a complication in the latter disease. It is also stated to be of prognostic import in tuberculosis, as the reaction does not appear until late in the course of the malady, and then persists until death. Typhoid urines gave a positive result with greatly diluted reagents, whereas tuberculous urines did not so respond.

#### An Ophthalmic Surgeon on Legal Evidence.

MR. MALCOLM McHARDY has on several occasions secured the sympathy of the medical profession on the way in which his name has been brought before the notice of the public. The first occasion was when the well-known professor of ophthalmology fell overboard from a yacht, and was rescued after a perilous immersion. This adventure was, we believe, recounted to the newspaper reporters by a friend unversed in the usages of the medical world. His most recent appearance in public is due to his own deeply rooted dislike to attendance in Court to give evidence on behalf of a litigant formerly under his care as a hospital patient. An appearance of that kind undoubtedly involves a good deal of inconvenience and loss to a busy consultant. Fortunately, it is rarely required, and in any case must be accepted as one of the drawbacks necessarily attached to the holding of a public post. As the Courts can compel the attendance of medical men attached to hospitals, we fail to recognise the pertinence of the indignant letter of protest which Mr. McHardy has written to the Editor of the *Times*. Such a remonstrance, moreover, would have been hardly less effective, and certainly would have been more in consonance with the traditions of the medical profession, had it been signed with a *nom de plume* instead of Mr. McHardy's name and an appended list of professional proofs.

#### The Chair of Surgery in Dublin.

AFTER forty years of service on the teaching staff of the School of Physic in Ireland, it is announced that Mr. Edward Bennett has begged to be relieved of part of the duties of the Chair of Surgery. From 1864 to 1873 he held the post of University Anatomist, and it is not too much to say that during most of that time he had practical control of the Department of Anatomy. To him, more than to any living man, is due the setting up of a high standard of teaching of that subject in Dublin, a standard maintained by his colleagues and successors, Macalister, Little, Brooks, and Cunningham. In 1873, he was appointed Professor of Surgery, and he still holds that post. The Board of Trinity College has, however, granted his request to be allowed to direct his teaching duties in theoretical and operative surgery, and to devote his time to the care of the surgical museum, of which he is curator. This museum contains a wealth of material, for the greater part collected and arranged by Mr. Bennett himself, and it is a matter of great importance that he will

(a) *Univ. Penn. Med. Bull.*, September, 1904.

now have leisure to complete the descriptive catalogue on which he has been long engaged. The completion of this work may be looked forward to as the consummation of his forty years' scientific work in Dublin. And it is with pleasure we learn that the Board of Trinity College has arranged for its publication in the University Press Series. Mr. Bennett intends still to continue his duties as Clinical Teacher and Surgeon at Sir Patrick Dun's Hospital. His old pupils all over the world, in whose respect and affection he holds the highest place, will join in wishing him many years of health and activity in the work he loves.

#### "Ether Day."

It is well that the world should keep green the memory of its benefactors, and the more so from the fact that the virtues of illustrious men are often ill-recognised and ill-rewarded during their lifetime. Perhaps one of the greatest of all human discoveries was the discovery of anæsthetics, to be ranked alone with that of antiseptic or aseptic surgery. On Monday, October 17th last, the celebration of the fifty-eighth anniversary of the first administration of ether as a surgical anæsthetic was held at the Massachusetts General Hospital, Boston. The amphitheatre, where the meeting took place, was arranged as nearly as possible to resemble its appearance on the historic occasion of October 16th, 1846. An address was delivered to a densely packed audience by Dr. J. Collins Warren, Mosely Professor of Surgery at Harvard University, the grandson of Dr. John C. Warren, who performed the first operation under ether. He detailed the facts of the discovery, which is still incorrectly described in many quarters. Mr. Jackson, scientific chemist at Boston, first suggested the use of ether as an anæsthetic to a dentist of the same city, Mr. Morton. The latter administered ether for the first time to a patient upon whom Dr. Warren operated in the Massachusetts Hospital. It would be a good idea to place a statue of Sir Humphry Davy alongside that of Dr. Warren and Sir James Simpson in a prominent place in London, as three of the greatest heroes of humanity and benefactors of mankind the world has ever known.

#### Death in "A Pleasant Confection."

WHATEVER views may be held by the medical profession as to their practical exclusion from the court of the London coroner, Mr. Troutbeck, it is clear that the newspaper reporter eagerly gleans the crumbs of wisdom that fall from that gentleman's table. It may be presumed, perhaps, that the natural sagacity attached to that particular species of hybrid legal inquiry is raised to an unimpeachable standard of authority because the medical evidence comes through the mouth of Dr. Freyberger, the Pathologist, or whatever his official title may be, of the London County Council. At an inquest last week the learned doctor stated that he had examined a chocolate cake similar to that administered to a deceased child of six and that it tasted like santonin, which was

often legitimately used as a medicine under certain circumstances, but should never be given except under medical directions. With the latter part of the statement every medical man will cordially agree. It is nothing short of a public scandal that dangerous drugs such as narcotics, irritants and corrosives should be sold wholesale to the public, often under the specious guise of "a pleasant preparation," as in the case under notice, or protected by a patent stamp. There is another side to Dr. Freyberger's evidence. Santonin has an extremely faint, bitter taste. If that were perceptible to Dr. Freyberger beneath the disguise of a chocolate cake, then, indeed, we begin to understand his claims to be considered a great pathologist. As a toxicologist the newspaper report does not mention that he applied the recognised tests for santonin, but Mr. Troutbeck, after all, has not had the benefit of a scientific education, and so would not be likely to cavil at the extremely difficult appeal to the sense of taste.

#### The Belt in Whooping-Cough.

AMONG those who are so unfortunate as to suffer from sea-sickness, one of the favourite methods of relief is the application of pressure over the stomach. There is no doubt that this lessens the tendency to continued vomiting, and the same principle has been applied with some success in the vomiting of pregnancy. More recently, Dr. Kilmer, of New York, has introduced the use of an abdominal elastic belt in the treatment of whooping-cough. He employs an elastic bandage reaching from the axillæ to the hips, keeping it slightly on the stretch. Underneath the elastic he first applies a stockinette binder to protect the skin. The results, both as regards cough and vomiting, are most satisfactory. In only one case out of eighteen did he fail to stop the vomiting, while in one-third of the cases the cough was either greatly lessened or stopped. That the sequence of events was really causal was shown by the recurrence of the cough and vomiting in one case when the belt was removed by the child's mother. The method is so simple in its application, and so entirely harmless, that it will doubtless receive a wide trial, and it may possibly prove of some use in the treatment of a troublesome condition.

#### Anæsthesia in Operations on the Naso-Pharynx.

THERE are certain surgical operations which, on account as well of their brevity as of their site, form, as regards the choice of a suitable anæsthetic, a class by themselves. These are the brief operations on the mouth, nose, and throat which rarely require more than two minutes' time available for work. Such are many dental operations, and such operations on the throat as removal of tonsils or adenoid growths and snaring of polypi. It is necessary in most of these cases for the anæsthetist to produce at the start a sufficient anæsthesia to carry the surgeon through the whole operation. When induction has been made, the anæsthetist removes his apparatus and

hands over the patient to the surgeon. Under the circumstances, great discrimination is necessary in the choice of an anæsthetic, and it is obvious that this will be governed by quite different considerations from those that obtain in other cases. Until recently chloroform has been on the whole the favourite agent, and there is no doubt that as regards quiet anæsthesia, freedom from irritation of the larynx and absence of coughing, it gives excellent results. It presents, however, the serious disadvantage that it can never be given in safety to a patient in the sitting posture, an attitude chosen by many surgeons, and that in any case it introduces the risk of sudden syncope. Nitrous oxide, while a perfectly safe anæsthetic agent, rarely gives the desirable quietude, and it gives an awkwardly brief anæsthesia. Mr. Luke, of Edinburgh, who has a large experience of anæsthetic work of this class, is inclined to leave the choice finally between ether and ethyl chloride. While the former is very constant in its action, it sometimes produces cyanosis with troublesome bleeding, and induces cough with consequent collection of mucus at the site of operation. Ethyl chloride, on the other hand, gives a calm and comfortable anæsthesia which by an adroit administrator can be made to last up to four minutes, though so long a time is rarely required. In addition, the patient recovers very quickly, and is seldom annoyed by vomiting or other troublesome sequelæ. On the whole, it would seem that ethyl chloride, either alone or in the mixture known as "somnoform," is the most suitable agent in this class of cases.

#### Folk-Medicine in Fife.

THE study of folk-medicine is not merely one of those hobbies, interesting and amusing, which add zest to the life of a medical man working in a country district. It is, if properly considered, a valuable contribution to historical psychology, exhibiting those peculiarities of point of view and of belief which are the remnants of a mental attitude of a much earlier era. Most items of folk-medicine as they are found at present belong in origin to one of two classes. They are on the one hand, charms, incantations, or sacrifices directed to the appeasement of gods or demons, or, on the other, crude precepts empirically derived. These latter, being judgments from experience, do not differ in kind from the practices of legitimate medicine, but merely in the degree of their scientific justification. In many customs, of course, the propitiatory idea and the judgment of experience are inextricably blended, and, indeed, the latter is always put forward as the ostensible reason of the practice. Dr. Rorie, of Fifeshire, in a recent collection (a) gives many interesting customs observed in his neighbourhood. A case of sacrificial cure is that of the application of three puppy dogs, split up and applied hot, to a septic arm. Though the animal varies, this custom has been noted practically all over the

world. A curious remedy for enuresis is the broth or powder made from boiled or roasted mice. A decoction of black slugs is a cure for rheumatism, and the juice of white slugs for phthisis. As in many other localities, the smell of fresh-turned earth is regarded as possessing peculiarly beneficial power, and miners suffering from exposure to impure air were made to lie with the face over a fresh-cut hole in the earth. If Dr. Rorie were not a good Scot, we should think he was poking fun at the good people of Fife when he tells us of the horror with which they regard "a rash drink o' water," and their belief in the various dangers which follow the incautious use of that dangerous and insipid fluid.

#### Aerophagy.

EVERY "horsey" man knows that one of the worst tricks a horse can learn is that known as "wind-sucking," or the swallowing of air, which, though not fraught with serious consequences, leaves the horse in unfit condition for violent exercise. Mathieu has recently drawn attention to a similar habit which exists in the human race, although the persons afflicted are rarely aware of the condition. In fact, they think that air is passing in the opposite direction, and they may complain of eructations. In the act of air-swallowing, the patient closes his lips, bends his head forward, and makes a swallowing movement, and if at the time the stomach be auscultated an explosive ringing sound is heard as the bubble enters it. If large quantities of air be swallowed, considerable distension, of course, occurs, until relief is given by a violent eructation. In fact the habit seems sometimes to spring from the attempt to produce this result. Where there is a moderate degree of flatulent dyspepsia, for instance, discomfort is relieved by the belching of wind, and swallowing of air may be a necessary antecedent of this act. Mathieu distinguishes several types of aerophagy, of which the most important are the dyspeptic and the hysterical. In the latter condition, enormous quantities of air may be swallowed quite silently and unconsciously, and may only become felt by the ensuing flatulence and tympanitis.

#### The Heart in Tuberculosis.

SINCE the announcement by Rokitansky, in 1846, of the theory of the supposed antagonism between valvular heart disease and pulmonary tuberculosis, many observers have sought to bring forward clinical evidence in its favour. It is generally believed that valvular disease affecting the left side of the heart has a more or less retarding influence upon the progress of chronic phthisis, or even that individuals so affected are to some extent exempt from the attacks of the tubercle bacillus. The explanation which has been offered for this antagonism is that a sort of immunity is conferred through the venous

(a) *Edin. Med. Journ.*, June, 1904.

stagnation and consequent chronic congestion which is maintained throughout the pulmonary circulation. That this "immunity" is by no means absolute, nor, indeed, constant, is proved by the fact that the concomitance of the two affections not infrequently occurs. Dr. G. A. Norris, (a) of Philadelphia, has found that smallness of the size of the heart, which was at one time thought to be an important predisposing cause of tuberculosis, is generally discovered at the post-mortem; but he considers that this may be equally the result of the generally impoverished condition of all the bodily tissues. On the other hand, patients suffering from pulmonary stenosis are exceedingly prone to contract phthisis, and this is not surprising when it is borne in mind that this particular cardiac lesion is frequently associated with congenital abnormalities which do not improve the general poorly aerated condition of the blood. Actual tuberculosis of the heart itself is decidedly rare, but it has been estimated that some degree of tuberculous endocarditis is met with in something under 5 per cent. of all cases of phthisis submitted to an autopsy. Degeneration of the cardiac muscle commonly occurs in pulmonary tuberculosis, which probably accounts for the failure of digitalis in many cases of phthisis.

#### The Influence of Attention upon Work.

As a state of consciousness, attention is psychologically considered to be that condition in which a single idea is predominant over all others. Active attention necessarily implies concentration of the whole mind upon the matter in hand, and without this no true mental impression can be made. Read in this light the popular phrase of "giving one's mind to one's work" has a deep psychological significance. The inattentive child, whose thoughts are instantly diverted by the buzzing of a fly or the patter of raindrops upon a window-pane, can no more hope to master his lesson than the student who habitually allows his mind to run off on side issues. Lack of concentration is fatal to success, especially in matters scientific, where secrets can be learnt only by steady and patient application. However desirable or attractive the quality of versatility, it must be kept under control by all who would seriously contribute to the sum of human knowledge. Many individuals of undoubted genius, of high mental qualities, are unable to undertake original research, simply because they cannot focus their undivided attention upon one topic. It is true, of course, that certain purely mechanical work may be performed practically without attention, as may be seen in the case of a pianist carrying on a conversation with a friend. But although manual work may be to a large extent independent of voluntary attention, it is also far better performed when directed and accompanied by mental processes. This fact has recently been scientifically confirmed by M. Féré, who, by taking ergographic records, has found that the working

capacity of the middle finger for weight-lifting is considerably impaired if the attention be concentrated upon some other part of the body. We have, therefore, a physiological basis for the Ciceronian dictum—"Quicquid agas, agere pro viribus."

#### Craniotomy.

A GOOD deal of discussion has been going on in various countries lately as to the performance of craniotomy on living children. In Protestant countries the view generally held is that there should be no hesitation in sacrificing the child's life if thereby the mother can be saved, whilst Roman Catholics are inclined to attach greater importance to the child's existence. In modern midwifery, though craniotomy is still much in vogue in delivering a child already dead, there is a considerable change in practice with regard to living children, now that Cæsarian section and symphysiotomy can be performed with such good prospects to both subjects. Whilst prepared to spare no effort to bring a living child into the world, most obstetricians would hardly go so far as to say with Pinard that embryotomy of the living child is a thing of the past. Strict surgical practice will, however, generally find itself in accordance with the moral dictates of the question, and the effort to spare both lives is usually made. How seldom embryotomy is necessary if skilled attendance is at hand is shown by the results of Veit's practice in the towns of Leiden, Erlangen, and Leipsic. In eight thousand deliveries conducted under his supervision he has never once had recourse to it, and he holds that it can always be avoided if the diagnosis of the obstructive condition is made sufficiently early. Veit has performed Cæsarian section twenty times, and symphysiotomy six times in his series of cases; and the fact that he has only lost two mothers and two children compares very favourably with the usual mortality results attached to embryotomy. Even those who are not prepared to agree with Veit, that embryotomy is never called for, cannot but congratulate him upon his success.

#### The Medical Diplomates of Scotland.

THE newly-formed Association of medical men holding one or more of the various diplomæ of the Scotch Colleges is the latest of the many bodies that have sprung up in the medical profession of late years. It has been formed mainly with an eye to the interests of practitioners in parts of the Kingdom other than Scotland, where it may be presumed that there is no need for protection. Medical practitioners holding these particular qualifications form a strong body in England, Wales, and Ireland. One of their chief grievances lies in the fact that they are excluded from the honorary staff appointments at most of the large hospitals, Metropolitan as well as provincial, outside Scotland. In London a flagrant example is to be found in the person of an accomplished assistant surgeon who, after

(1) *Amer. Journ. Med. Sci.*, October, 1904.

twenty years' service, was kept out of the full surgeoncy because he did not hold an English qualification. A similar injustice is repeated again and again in many a provincial town and country hospital. Subscribers to medical charities cannot be expected to understand the slur they cast upon honourable men by enforcing restrictions worthy of a trades union rather than of a liberal profession. It is to be hoped that the new Association will succeed in throwing open all hospital appointments to Scotch, and, incidentally, also to Irish Diplomates. Among its Vice-Presidents are Professor Clouston, Sir Patrick Heron Watson, Sir J. Halliday Croom, Sir Alfred Cooper, Sir James Clark, Sir Anderson Critchett, Sir John Reed, Sir John Sibbald, Sir John Tyler, and Sir William Whitla. Full information as to the objects and proposed work of the Association may be procured from the energetic Honorary Secretary, Mr. Heather Bigg, F.R.C.S., 56 Wimpole Street, London, W.

#### PERSONAL.

THE health of the Prince of Wales at the end of last week formed the subject of detailed sensational statements in certain newspapers, the editors of which have not hesitated to assert that consumption was detected some years ago in the Royal patient by Sir Frederick Treves—a surgeon, by the way—just before the Prince's voyage in the *Ophir*. The rumour—on the face of it ridiculous—has been already officially contradicted.

SIR WILLIAM MITCHELL BANKS, M.D., F.R.C.S., of Liverpool, who died in August last, has left estate of the gross value of £23,527 11s. 2d., including net personally sworn at £21,642 19s. 5d. By his will, dated July 5th, 1887, his widow is appointed sole executrix.

At a recent meeting of the Australian State Cabinet, Dr. W. E. Jones, superintendent of the Brecon and Radnor Asylum, was appointed Inspector-General of the Asylums for the Insane in Victoria.

DR. H. E. SCOWCROFT has resigned the appointment of District Surgeon of Raub, Pahang, Federated Malay States.

DR. J. M. RHODES, Chairman of Committee, recently laid the foundation stone of the buildings of the Colony for Sane Pauper Epileptics at Langton, near Blackburn, the first of its kind established in the United Kingdom.

THE President of the Seventh French Medical Congress, recently held in Paris, was the famous pathologist and histologist Professor Cornil.

At the French Congress one of the most important communications was that of Professor Chantemesse on "The Serum-therapy of Enteric Fever," by which method he claimed to have reduced the mortality to 1 per cent.

THE new Belfast Maternity Hospital was opened on Monday, November 7th, by the Countess Grosvenor.

THE winter session inaugural address of the Royal Medical Society of Edinburgh was delivered on October 28th last by Sir James Crichton-Browne.

At a meeting on November 1st, of the Faculty of Medicine of the University of London, Mr. Butlin delivered his valedictory address on his retirement from the office of Dean, a position which he resigns by

virtue of a rule that limits the period of office to four years.

DR. JAMES KINGSTON-FOWLER was, at the same meeting, unanimously elected to the important post of Dean of the Faculty of Medicine of the University of London.

MR. A. PEARCE GOULD was at the same time elected Vice-Dean of the Faculty.

DR. P. H. PYE-SMITH has been reappointed representative of the University of London on the General Medical Council.

MR. FRANCIS GALTON, F.R.S., has endowed a Fellowship in the London University for the promotion of the study of eugenics, defined as "the study of the agencies under social control that may improve or impair the racial qualities of future generations, either physically or mentally."

ON St. Luke's day last, October 18th, Sir John Banks, K.C.B., attained his sixtieth year of Fellowship of the Royal College of Surgeons of Ireland. Although Sir John has for some years retired from active participation in the affairs of the College, he still takes a keen interest in its welfare. At the meeting of the College held on Friday last a resolution of congratulation on the occasion of the diamond jubilee of his election to the Fellowship was carried by acclamation.

SIR CHARLES BALL, F.R.C.S., has resigned the office of representative of the Royal College of Surgeons in Ireland on the General Medical Council. We are informed that Mr. Swanzy, whose name as an ophthalmic surgeon is well known, and who is the present vice-president of the College, and Sir Thomas Miles, ex-president of the College, have offered themselves as candidates for the office.

DR. CECIL SHAW has been appointed lecturer on ophthalmology and otology in the Queen's College, Belfast, in succession to the late Dr. McKeown. Dr. Shaw already holds the posts of Assistant-Surgeon at the Belfast Ophthalmic Hospital, and of Ophthalmic Surgeon to the Mater and Ulster Hospitals.

PROFESSOR LORRAIN SMITH, who is leaving Belfast to take up his appointment at the Victoria University, Manchester, was on Thursday last presented by his colleagues and friends with a handsome souvenir at a complimentary dinner, particulars of which will be found in the letter by our Belfast correspondent.

WE learn that the teaching duties of the Chair of Surgery in Trinity College, of which Professor Bennett has been relieved, have been committed to Mr. Edward H. Taylor, F.R.C.S.I., Examiner in Anatomy to Dublin University, and Surgeon to Sir Patrick Dun's Hospital.

PROFESSOR WINDLE's resignation of the Birmingham chair of anatomy was formally communicated to the council of the University at its last meeting, when the following resolution was unanimously passed:—"That the Council receives the resignation of Dr. Windle with regret, and, while congratulating him on his important educational and administrative appointment in Ireland under the Crown, takes the opportunity of thanking him for his long and distinguished services to the School of Medicine in Mason College and to the Medical Faculty of this University, both as dean and as professor, as well as to the general cause of higher education in the Midlands."

#### Harvelian Society of London.

THE annual dinner of the society will be held at the Monico Restaurant on Thursday, November 24th, at 7 for 7.30 p.m. The chair will be taken by the President, Dr. C. Theodore Williams.

## Special Correspondence.

FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND.

GLASGOW OPHTHALMIC INSTITUTION.—On the 1st inst. a course of post graduate lectures and demonstrations was inaugurated by Dr. A. Maitland Ramsay, who delivered an instructive address on "Eye-strain and its Consequences." The lecture was illustrated by means of lantern-slides, microscopic preparations, the opaque projector, and by Kuhne's optical box. Mr. Hedderwick, the chairman of managers of the Glasgow Royal Infirmary, presided, and expressed his gratification at the large attendance of medical men, as showing that the Institution was not only an agent for the relief of suffering, but was also fulfilling an educational purpose in the City.

### BELFAST.

COMPLIMENTARY DINNER AND PRESENTATION TO PROFESSOR LORRAIN SMITH.—A farewell dinner to Professor Lorrain Smith, on the occasion of his leaving Queen's College, Belfast, for Victoria University, Manchester, was held in the Grand Central Hotel, Belfast, on Thursday evening, November 1st. The President of Queen's College presided, and practically all Dr. Smith's late colleagues at the College and at the Royal Victoria Hospital, Belfast, were present, as well as many of his past pupils and lay friends. After the usual loyal toasts the President proposed the toast of "Our Guest." In doing so, he contrasted the state of pathological teaching in Belfast ten years ago, when Dr. Smith was appointed, and now, when, thanks to the munificence of the late Sir James Musgrave, they had an endowed professorship, and through the joint action of the Government and the college, a proper building had been provided, with rooms for lectures, research, &c., and modern appliances. No small share in these changes was, he said, due to Professor Lorrain Smith, who had also made that laboratory an ultimate court of appeal on medical questions from all Ulster. The Civic authorities, too, had availed themselves of Dr. Smith's services, and he had been called in as an expert in various difficult questions regarding the prevalence of typhoid, the contamination of water, and the disposal of sewage. President Hamilton also referred to Dr. Smith's help on the College Council, the Victoria Hospital, and on the examining board of the Royal University, and concluded by wishing him all success in the new sphere to which he was going.

The toast having been enthusiastically honoured, Dr. Smith, in reply, explained that the founding of the School of Pathology had only been possible by the greatest self-sacrifice on the part of the other teachers of the medical school, for the funds at the disposal of the school were so small that the necessary money for outfit and upkeep could only be got by stinting other departments. In spite of that, the new department was administered in no grudging spirit, and never a word of complaint reached him. To the men in the college who spent their lives working for their departments, and whose lifework was being crippled by the absence of funds, he wished to make on that occasion the fullest and heartiest acknowledgment. But for their self-sacrifice and public spirit the medical school would that day have been without anything worthy of the name of a pathological department. It was a matter of pride to him that during his term of office about one hundred post-graduate students passed through the department, and a number of them stayed to work at research as long as their time permitted.

Dr. R. J. Johnstone then presented Dr. Smith with a solid silver tray, on which was inscribed: "To Professor Lorrain Smith, from his old friends and pupils at the pathological laboratory, Queen's College, Belfast, 1895-1904." He explained that this was not from the medical profession generally, but just a souvenir from some of the men who had enjoyed many happy hours of work, tempered by the fumes of tobacco, in the laboratory. Dr. Johnstone dwelt specially on the

research work carried out by Dr. Smith's pupils, and the enthusiasm with which he fired them, and the way in which the school acquired under his guidance a character of its own. As an instance, he mentioned Dr. Houston's work on the pathology of the blood.

Dr. Smith, in reply, thanked his old friends and pupils very warmly, and dwelt on the happy fellowship of the laboratory workers all through his time at the college. The first worker with him had been Dr. Cecil Shaw, whom he was glad to congratulate on his recent appointment on the College staff, as lecturer on ophthalmology. Others, too numerous to mention by name, had followed, and many continued to work during all the time he was there. He had the utmost pleasure in receiving the handsome piece of plate, and thanked them all for the kind sentiments expressed on their behalf by Dr. Johnstone.

APPOINTMENTS TO THE ROYAL VICTORIA HOSPITAL. The following appointments have been made at this hospital: Drs. Crymble, Davis, and Killen to be house surgeons; Dr. Lowry to be house physician; Dr. McIlwaine to be medical registrar; Dr. Irwin to be surgical registrar; Dr. H. Stevenson to be hon. anaesthetist; and Dr. Beattie to act as temporary pathologist to the hospital.

## Correspondence.

### THE TREATMENT OF INOPERABLE CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Had Dr. Mackenzie read my letter a little more carefully he would have seen that I was claiming nothing, and it was therefore unnecessary for him to say that he did not wish to deprive me of any credit. All I desired to do was to correct the impression which you, Mr. Editor, and others had received, that he was the pioneer in the treatment of cancer of hypodermic injection. I do not agree with the correctness of the statements in Dr. Mackenzie's letter; but I need not trouble you with such trivial matters except to say that I do not know why Dr. Mackenzie appears to be so annoyed with me, as I gave him full credit for his work with Merck's iodipin on the only occasion I published anything on the subject. It is, however, necessary to refer to Dr. Mackenzie's last sentence in which he asks me "in justice to himself and others," to publish now what I was using nearly two years ago. Why in justice to him I cannot imagine, as he already knows what I was experimenting with, but his curiosity will perhaps be gratified when I tell him that at present I am experimenting with arsenic. It would never occur to me even to think of publishing with only the support of two cases, one dead and the other—nature of tumour apparently not diagnosed—under treatment for less than two months! Besides, I do not wish to run the risk of having an objectionable advertisement in one of the Sunday papers as Dr. Mackenzie has had to put up with. My brother and I have had better results at the beginning of more than one experiment, and when Dr. Mackenzie has had a few more unsuccessful cases he will not be so ready to publish what he hopes, but will wait until he knows. In this work one may hope for success, but must expect disappointment. There have been too many "cures" lately—salt, molasses, violets, Schmidt, mulyptol, &c., and I regret that Dr. Mackenzie is trying to add to their number on such very insufficient grounds. Doctors understand the value of such evidence, but readers of the *Dispatch* do not.

I am, Sir, yours truly,

GEORGE E. KEITH.

7, Manchester Square, W., Nov. 4th, 1904.

### THE LACK OF PRACTICAL METHODS IN SURGICAL TEACHING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to see that Mr. Edmund Owen does not feel well pleased with the present state of things in the practical work of our medical schools and education. Nowadays many men are beginning to find out that the system that has grown up during the past

forty years or so is not satisfactory. To what extent they have to thank themselves for this we can leave them to consider. There is one thing quite certain, and that is they did nothing to stop it. There has been no proper clinical teaching in our hospital schools, and specialism has been preferred.

The consequences are beginning to be felt, and it is well for those who find fault to look to what they did themselves to prevent. Mr. Edmund Owen and many like him let things go in a good-tempered, indifferent way, and now they deservedly suffer.

I am, Sir, yours truly, R. L.  
Kensington, Nov. 1st, 1904.

#### MUNICIPAL DENTISTRY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is impossible to deny the fact that at the present day a considerable proportion of children of every class display signs of dental degeneration, and that among the poor these signs, as well as the presence of decayed teeth, are more common; but, statistics having been accumulated only within recent years, and this to a partial extent only, there exists no scientific basis whatever for the opinion that dental deterioration is extending or that dental caries is more prevalent among the present than former generations. It seems a little grotesque to read that in St. Petersburg nine municipal dental institutes have been set up, whilst the population throughout Russia is allowed to live in sanitary surroundings worse than Oriental, and to suffer from periodical preventable famine with epidemic diseases due to filth and want. It will be not much less ludicrous if we in England follow this example before setting to work to remove the first causes of the evil, and to apply remedies which shall result in production of a race showing physical superiority in every direction, including the teeth. In this way it would pay better first to establish municipal dairies where the poor could obtain milk up to a high standard of quality and purity. Rickets, one of the commonest causes of tooth decay, is largely due to lack of proper food in the way of milk. In many municipalities, especially where tradesmen dominate the local authority, the Food and Drugs Acts are either very slightly attended to, or altogether ignored; and the poor are supplied with milk of the most inferior quality. Reform of these abuses is more urgently called for than municipal dentistry. The housing question, the question of educating poorer class mothers in elementary knowledge of hygiene and the feeding of infants, and many other questions of the same kind, all under discussion at the present moment, and all bearing upon the subject of physical deterioration—all these questions call for attention and solution before provision of municipal dentistry is brought to the front. The question of providing meals for ill-fed school-children, which has lately been dealt with in an important correspondence in the *Times*, seems also somewhat more urgent than municipal dentistry. Money is needed for coercion of neglectful parents, and perhaps for provision of food and cooking arrangements at the schools. To starving children good teeth are not the most urgent necessity. Municipal dentistry is not more urgently called for than—for one example out of fifty—municipal hair-cutting and head cleansing. I could name a village in Surrey at this moment in which the majority of the children are affected with ring-worm, which prevents them from attending school. This has spread so widely in consequence mainly of the foul and often verminous conditions in which the unkempt heads of the children are habitually left by their careless parents. Many of these children are suffering from adenoids and chronic nasal catarrh caused in great measure by the damp, dark and unwholesome dwellings in which they are lodged. If local governing bodies are to spend more money, it ought surely to be on matters of prime importance, not upon grandmotherly projects such as municipal dentistry.

I am, sir, yours truly,

HENRY SEWILL.

## Obituary.

MR. HERBERT WILLIAM ALLINGHAM, F.R.C.S. ENG.

TELEGRAPHIC information has been received from Marseilles announcing the death by misadventure, on the 4th inst., of Mr. Herbert William Allingham, F.R.C.S., of 25, Grosvenor Street, London, while on his way to Egypt for the benefit of his health. He was the eldest son of the eminent surgeon, Mr. William Allingham, F.R.C.S., who is still living, and was born on April 17th, 1862. After receiving his education at Chatham House School, Ramsgate, and University College School, London, he entered as student at St. George's Hospital, where, at the time of his death, he held the position of Senior Assistant Surgeon and Lecturer on Operative Surgery. He became M.R.C.S. Eng. in 1882 and F.R.C.S. in 1887. In 1889 he married Fraulein Alexandrina von der Osten, who died in January of the present year. Her death was most keenly felt by him, and the breaking down of his health dates from this bereavement, from the effects of which, he confessed to the writer of these lines a short time since, he was quite unable to free himself, and the profession which he had loved and pursued with so much enthusiasm had ceased to possess the same interest for him. His professional career was one of exceptional brilliancy, and his reputation as an operator of great skill and judgment was world-wide. He held the position of Surgeon to the Household of his Majesty the King when Prince of Wales, and was subsequently appointed Surgeon to the Household of his Majesty the King. He was also Surgeon in Ordinary to his Royal Highness the Prince of Wales, and one of the Honorary Surgeons to King Edward VII.'s Hospital for Officers. Mr. Herbert Allingham was formerly surgeon to the Great Northern Central Hospital, and assistant surgeon to St. Mark's Hospital for Fistula. He was the author of several valuable works, that on "Diseases of the Rectum" having reached the seventh edition, and his

new work on "Operative Surgery," has proved a distinct success. He had also in the press another brochure on "Appendicitis."

The untoward death of Herbert Allingham from an overdose of morphia in the zenith of his professional career will come as a profound shock to the medical world as well as to a large and distinguished circle of friends. Although a young man he had already years ago achieved brilliant success whether judged from social or professional standpoints. Following in the footsteps of his father he early specialised in the direction of rectal surgery. His book on the "Diagnosis and Treatment of Diseases of the Rectum" has become a classic. He made numerous other important contributions to medical literature, and was a member of various learned societies. By his death the profession has been deprived of one of the most brilliant surgeons of the younger generation.

#### MEETING OF THE GENERAL MEDICAL COUNCIL.

We are officially informed that the Autumn Session of the General Medical Council will be held at the Office of the Council, at 2 p.m., on Tuesday, 22nd inst., and following days, at which Sir William Turner, K.C.B., will preside.

#### Literature.

##### HAMILTON ON "RAILWAY AND OTHER ACCIDENTS." (a)

THIS much-needed book supplies a gap in medical literature, and, moreover, fulfils that function in an effective fashion. The author has written for lawyers as well as for medical men—two professional classes that require special information on the matter of real and imaginary and pretended disorders of traumatic origin. The subject is, of course, a complicated one. The interests of the plaintiff as well as of the defendant must, of course, be protected. The shock of a railway accident, moreover, may upset the mental balance of a sufferer, and so inflict one of the many remote injuries for which a railway company may be called upon to make compensation. A finer degree of partial mental injury may present a knotty point for protracted legal discussion. We heartily endorse the author's position when he says:—"The time has certainly come for some one who is initiated, and has sufficient knowledge to urge the proper and honest presentation of medical facts in Court by the plaintiff as well as by the defendant, for it does not do to pervert medical truths, which in their way are quite as settled as the axioms of law." The absolute necessity of special knowledge and caution can be gathered from the experience of an English physician in over two hundred alleged railroad injuries. Of these thirty-two were frauds or cases of wilful exaggeration, twenty-one substitution cases in which there was a history of gout, phthisis, chronic epilepsy, alcoholism "female diseases," or conviction of previous ill-health; six women alleged that the symptoms of the menopause were due to injury; three had been in previous accidents, seven were the subjects of fright or suggestion, and one case of glycosuria was attributed to an accident, but was shown to be of previous origin; and in another old syphilis was made to do duty; in one case, in which insanity was claimed to be the result of an accident, it was proved to have antedated it. In forty-four there is a history of "no exaggeration," or the patient made a moderate claim; of the above cases, therefore, it will be seen that in at least two-fifths there was a suspicion of fraud. This is the best book we have seen on the subject, and it must at once take a high place of authority and reference.

(a) "Railway and Other Accidents." By A. M. Hamilton, M.D., late Clinical Professor of Mental Disease in Cornell Cottage Hospital, &c., &c. London: Baillière and Cox. 1901. Price 5s. net.

##### TEXT-BOOK OF CLINICAL ANATOMY. (a)

By the time the student has reached the study of clinical medicine and surgery, his anatomical acquisitions, cumbered as they too often have been by details which have little practical bearing, are apt to be relegated to the garret of his mental equipment, and the fact that in his ward work he receives instruction in "medical" (not to speak of "surgical" and "gynæcological") anatomy tends to lead him to divorce the systematic knowledge he has so laboriously acquired from everyday work, while when his memory requires refreshing he too readily tends to refer to some convenient diagram in a book on clinical diagnosis rather than wade through the pages of an anatomical text-book, seeking for the grain of information among an intolerable heap of, to him, now useless facts. That this is not as it should be is daily more and more being recognised by anatomical teachers, who now pay much greater attention to applied and topographical anatomy than, say, a decade ago, and the volume now before us is an expression of this. The author has essayed, and to a large extent succeeded, in giving a complete presentment of the main facts of clinical anatomy, surgical and medical, within a comparatively reasonable compass. No doubt the anatomist might find errors of detail or slight descriptive inaccuracies, but from the clinician's standpoint the volume is almost wholly satisfactory. Dr. Eisendrath naturally pursues the regional method, and in each section tells the student what he can feel with his fingers and see with his eyes, before proceeding to describe deep structures and their relations. We note with satisfaction that throughout the book sufficient attention is paid to the anatomical peculiarities of the child. The rather dry bones of anatomy are partially, at least, clothed and resuscitated by references to clinical symptoms and pathology generally, and while we admit the importance of this in giving a live interest to the pages of facts, we are not sure but that the size of the book might have been reduced without affecting its usefulness by a judicious curtailment, both of these clinical details and of some of the short descriptions of operations. The illustrations throughout maintain a high level of merit, but here again the pathological ones, few as they are, might for the most part have been omitted without any great loss. We had hoped to find greater use made of radiographs. A few plates showing the ossification of some of the chief epiphyses at different ages, for example, could readily have been obtained, and would have given information which generally requires a good deal of search when it is wanted. Another omission which strikes us is the inadequate space given to the anatomy of the nervous system; there is, for instance, no drawing of the base of the brain—one to which a student often wishes to refer—and cerebral topography in general is scantily dealt with. Assuredly the student will not get enough anatomical information to be of service in the diagnoses of nervous cases from Dr. Eisendrath. When a second edition of the book is called for, as we are sure it will be, we trust that space, which could easily be got by a judicious condensation of the pathological information, will be found to rectify the omissions referred to, when the student will have in one volume a most convenient work of reference to which he will rarely turn in vain.

##### NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

- THE ABERDEEN UNIVERSITY PRESS, LTD. (Aberdeen).  
University of Aberdeen—Proceedings of the Anatomical and Anthropological Society, 1902-1904. Illustrated. Pp. 155.  
EDWARD ARNOLD (London).  
Lectures on Diseases of Children. By Robert Hutchison, M.D., F.R.C.P. Pp. 338. Price 8s. 6d. net.  
ASHER AND CO. (London).  
St. Louis, 1904. German Educational Exhibition. Medicine. Pp. 169.

(a) "A Text-book of Clinical Anatomy." By Daniel M. Eisendrath, Professor of Clinical Anatomy in the University of Illinois Philadelphia: W. B. Saunders and Co. 1904. 21s. net.

- BAILLIÈRE, TINDALL AND COX (London).**  
 Handbook of Diseases of the Ear. By Richard Luke, F.R.C.S.Eng. Second Edition. Illustrated. Pp. 242. Price 6s. net.  
 The After-Treatment of Operations. By Lockhart Mummery, F.R.C.S.Eng., B.A., M.B., etc. Second Edition. Illustrated. Pp. 240. Price 5s. net.  
 The Nutrition of the Infant. By Ralph Vincent, M.D. Second Edition, revised and enlarged. Pp. 321. Price 10s. 6d. net.  
 Guide to the Examination of the Throat, Nose, and Ear, for Senior Students and Junior Practitioners. By William Lamb, M.D., C.M.Édin., etc. Illustrated. Pp. 152. Price 5s. net.  
 Malignant Diseases of the Larynx (Carcinoma and Sarcoma). By Philip R. W. De Sauti, F.R.C.S. Pp. 107. Price 4s.  
 Aids to the Study of Sanitary Law. By Harry Critchley, M.A., M.D., D.P.H., etc. Pp. 82. Price 2s. 6d., cloth, 2s. paper.  
 Burden Camels; Their Management and Diseases. By H. M. Lenox-Conyngham, Capt. A.V.D. Pp. 24. Price 1s. 6d. net.  
 Transactions of the Medico-Legal Society for the Years 1902, 1903, and 1904. Edited by Stanley B. Atkinson, M.A., M.B., Vol. I. Pp. 100. Price 7s. 6d.
- JOHN BALE, SONS AND DANIELSON, LTD. (London).**  
 Medical Hints and Notes on Egypt as a Winter Resort. By Arthur J. M. Bentley, M.D. Pp. 43. Price 1s.  
 Notes on Assouan. By G. Dundas Edwards, M.A., Camb., M.R.C.S., etc., etc. Pp. 36. Price 1s. net.
- JOHN BEVAN AND SONS (Torquay).**  
 Letters on Health and Happiness. By John A. Bevan, M.D., Pp. 68. Price 2s. 6d. net.
- ARCHIBALD CONSTABLE AND CO., LTD. (London).**  
 Clinical and Pathological Observations on Acute Abdominal Diseases. By E. M. Corner, B.Sc., Lond., etc., etc. Pp. 98. Price 3s. 6d. net.  
 The Surgery of the Diseases of the Appendix Vermiformis and their Complications. By Wm. Henry Battle, F.R.C.S., and E. M. Corner, M.B., etc., etc. Pp. 208. Price 7s. 6d. net.
- J. AND A. CHURCHILL (London).**  
 Urine Examination Made Easy. By Thomas Carruthers, M.A., M.B., Ch.B. Pp. 32. 1s. 6d. net.
- CORNISH BROS. (Birmingham).**  
 On the Sterilisation of the Hands. By Charles Leedham-Green, M.B., F.R.C.S. Pp. 102. Price 2s. 6d. net.
- CHARLES GRIFFIN AND CO., LTD. (London).**  
 Text-book of Human Physiology. By Dr. L. Landois. Fifth Edition. Illustrated. Pp. 1027.
- H. K. LEWIS (London).**  
 Medical Electricity: A Practical Handbook for Students and Practitioners. By H. Lewis Jones, M.A., M.D. Fourth Edition. Illustrated. Pp. 536. Price 12s. 6d. net.  
 Deaths in Childbed; A Preventible Mortality. By W. Williams, M.A., M.D., etc. Pp. 99. Price 2s. 6d. net.
- LONGMANS GREEN AND CO. (London).**  
 The Essentials of Chemical Physiology. By W. D. Halliburton, M.D., F.R.S. Fifth Edition. Pp. 236. Price 4s. 6d. net.
- FRANK F. LISIECKI (New York).**  
 The Surgical Treatment of Bright's Disease. By George M. Edebolis, A.M., M.D., etc. Pp. 327.
- THE LONDON ARGUS LIBRARY OF FICTION (London).**  
 A Sparrow, a Mouse, and a Man. By George H. R. Dubbs, M.D. Pp. 68. Price 6d.
- LONDON COUNTY COUNCIL (London).**  
 The Fifteenth Annual Report of the Asylums Committee and the Sub-Committees for the year ending March 31st, 1904. Pp. 230. Price 2s.
- MACMILLAN AND CO., LTD. (London).**  
 The Food of the Gods and How it Came to Earth. By H. G. Wells. Pp. 217. Price 6s.
- GEORGE FITMAN AND SONS, LTD. (London).**  
 The Blind Man's World; An English Version of Entre Avengles. By Dr. Emile Javal. Translated by W. Ernest Thomson, M.A., M.D. Pp. 158. Price 3s. net.
- REBMAN, LTD. (London).**  
 The Diseases of Women. By J. Bland-Sutton, F.R.C.S.Eng., and Arthur E. Giles, M.D., etc. Fourth Edition. Illustrated. Pp. 520. Price 11s. net.
- ST. ANDREW'S AMBULANCE ASSOCIATION (Glasgow).**  
 Home Nursing and Hygiene. By J. Wallace Anderson, M.D., and George H. Edington, M.D. Pp. 156.
- W. B. SAUNDERS AND CO. (Philadelphia).**  
 A Text-Book of Clinical Diagnosis by Laboratory Methods. By L. Napoleon Boston, A.M., M.D. Illustrated. Pp. 549. Price 18s. net.
- SUDAN GOVERNMENT (Khartoum).**  
 First Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By the Director, Henry Balfour, M.D., B.Sc., etc. Pp. 88, with Coloured Plates.
- TAYLOR AND FRANCIS (London).**  
 Calendar of the Royal College of Surgeons of England, August 1st, 1904. Pp. 350.
- UNIVERSITY PRESS (Liverpool).**  
 Liverpool School of Tropical Medicine; Memoir XIII. Reports of the Trypanosomiasis Expedition to the Congo, 1903-1904. By J. E. Dulton, M.B.; J. L. Todd, M.D.; and C. Christy, M.B. Pp. 112.
- JOHN WRIGHT AND CO. (Bristol).**  
 An Introduction to Dermatology. By Norman Walker M.D. Illustrated. Pp. 284. Price 9s. 6d. net.

### Laboratory Notes.

#### B. EUCAIN LACTATE (SCHERING.)

A PREPARATION manufactured by Messrs. Schering of Berlin, at the suggestion of Professor Langgaard, to take the place of eucaïn and cocain. It combines the advantages of the low toxicity associated with eucaïn with a high degree of solubility—up to 29 per

cent. in water at room temperature. B. eucaïn lactate is a white non-hygroscopic powder very readily soluble in hot water; less so in cold. The eucaïn base in this salt is somewhat less than in the ordinary B. eucaïn; thus slightly stronger solutions are necessary. The London agents are Messrs. A. and M. Zimmermann.

#### THE SCHLEUSSNER X-RAY PLATES.

WORKERS with the X-rays are always on the look-out for a good plate, which, when found, is a treasure indeed. We have been asked to test the Schleussner plates, and have much pleasure in stating that for all-round X-ray purposes they are as good as any that have come under our notice. At the same time the price is not excessive, a drawback that applies to several sensitive plates specially introduced for this special kind of work. We have tried the Schleussner plate with various developers, and personally have obtained the best results with ordinary "pyro" developer, with which we have obtained beautifully modulated but clear pictures. The excellent illustration which appeared on page 460 of THE MEDICAL PRESS AND CIRCULAR (November 2nd, 1904) was taken on one of these plates, which are placed on the market by Messrs. Christy and Co., and may be purchased from the usual vendors of photographic plates. We should advise all radiographers to give them a trial.

#### MESOTAN.

A NEW salicylic remedy for the external treatment of rheumatic affections has been introduced by the Bayer Company. The remedy is mixed with an equal quantity of olive oil and brushed on the affected part several times daily. It is said to relieve pain and have a curative effect upon all pain of a rheumatic origin. The success obtained by Continental authorities with Mesotan certainly warrants an extensive trial by medical men in the United Kingdom. It is described by the manufacturers as a substitute for gaultheria oil, but it has a far less pronounced odour and is of greater facility of absorption.

### Medical News.

#### The Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity and Life Assurance Society, was held at 429, Strand, London, W.C., on the 28th ult. There were present Dr. de Havilland Hall, in the chair; Dr. Walter Smith, Dr. M. Greenwood, Mr. F. S. Edwards, Dr. W. Knowsley Sibley, Dr. A. J. Rice Oxley, Mr. H. P. Symonds (Oxford), Dr. Fredk. S. Palmer, Mr. Edwd. Bartlett, Dr. J. Brindley James, Dr. St. Clair R. Shadwell, Dr. F. J. Allan, Dr. J. W. Hunt, and Dr. J. B. Ball. The amounts showed a great improvement in the sickness claims, which were unusually heavy in the early part of the year. Since June the amount paid away has been appreciably under the expectation, and there is little doubt that the whole year's working will show a good margin in favour of the Society. On the other hand the general depression in business which has been somewhat severely felt by many members of the medical profession, shows itself in the lowered numbers of new members joining the Society. The last two years have been exceptionally good in this respect, and there is no reason to fear that as soon as the present temporary depression has passed away the social advantages to be obtained by joining the Society will not induce a large number to join it. Prospectus and all information on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

#### Central Midwives Board.

At the last meeting of this Board (a report of which appeared in our last issue) a scheme of examinations was adopted of which the following are the most important provisions:—A list of examiners, subject to annual revision by the Board, both for London and the provinces, shall be prepared by the Central Midwives Board from those who are willing to serve and

act, when required, by the Board. Examinations will be partly oral and practical, and partly written, and shall be conducted by not fewer than two examiners. The first examination will be held in July, 1905, and future examinations four times a year, or oftener if necessary, in London and the provinces, simultaneously on the same papers. The first provincial centres are to be Bristol, Manchester, Newcastle-on-Tyne. The remuneration of an examiner is fixed at the rate of seven shillings for each candidate examined. The scheme further provides that the examiners, both London and provincial, shall be invited to meet at the offices of the Central Midwives Board as often as may be necessary, and that the duties of the London examiners shall be (a) To consider examination questions suggested by provincial examiners; (b) to set all the papers of examination questions both for London and the provinces. Two of the examiners, with the assistance of one of the medical members of the Central Midwives Board to be appointed for the purpose, shall undertake this duty in rotation. The remuneration of the examiners shall, in respect of this duty, be two guineas each; (c) to conduct the examination, written and oral, of all candidates presenting themselves for examination in London; (d) to report to the Central Midwives Board the result of each examination held in London. From these regulations it appears that the principal duty of the provincial examiners is to set examination questions, and that these questions are to be then censored by the London examiners, and presumably, if thought suitable, are then to be made use of. We confess that we are unable to understand how any provincial obstetrician of repute could accept the post of examiner under such conditions. It may, be, however, that the regulations given above are capable of another interpretation from that which the phraseology necessitates.

#### Royal Ear Hospital.

THE new premises of the Royal Ear Hospital in Dean Street, Soho, are now completed, and the out-patient department is in full swing. With regard to out-patients special care has been taken on the one hand to secure the comfort of the patients, who are seen singly, and on the other to provide the surgeons with every modern up-to-date contrivance both for diagnosis and for operative and general treatment. The in-patients' department, which will shortly be opened, consists of three wards, one for children, one for women on the first floor, and one for men on the second floor. Alongside the latter is the operating theatre, which boasts of capital natural light, and is, of course, replete with all the necessary appliances of modern surgery. The children's ward has a high dado, which, dealing with nursery rhymes, should have a most soothing effect on the little sufferers. This hospital, which claims to be the oldest institution for the special treatment of aural and allied diseases, not only in this country but in Europe, was originally founded as far back as 1816 in Dean Street, Soho, under the name of Royal Dispensary for Diseases of the Ear; in 1876 it migrated to Frith Street, and in 1883 the Committee opened a department for in-patients. It is computed that upwards of 150,000 patients have received advice and treatment at the institution since its foundation.

#### Irish Medical Schools' and Graduates' Association.

THE autumn general meeting of this association will be held at the Hotel Cecil, Strand, on Tuesday, November 22nd, at 6.30 p.m. The autumn dinner will be held on the same evening, when the association will dine at the Grand Hall of the Hotel Cecil, at 7.30 p.m., the President, Surgeon-General C. Sibthorpe, C.B., in the Chair. The hon. secretaries will be glad to forward forms of application for membership to members who may have friends to propose for election to the association. New members joining on November 22nd may attend the dinner.

#### Royal College of Surgeons in Ireland.

THE lectures of the Winter Session commenced on Tuesday, November 1st. The prizes of the previous

session were distributed by Mr. Arthur Chance, president, as follows:—

*Barker Anatomical Prize*—£31 10s., C. Cooper.

*Mayne Scholarship*—£15, A. N. Crawford.

*Carmichael Scholarship*—£15, J. Preadiville.

*Gold and Silver Medals in Operative Surgery*.—Gold, J. S. Dunne; silver, P. D. Sullivan and J. C. Murphy (equal).

*Stoney Memorial Gold Medal in Anatomy*.—J. Preadiville.

*Descriptive Anatomy—Junior*.—D. P. Clement, first prize (£2) and Medal; G. S. Levis, second prize (£1) and certificate. *Senior*.—D. Adams, first prize (£2) and Medal; P. G. M. Elvery; second prize (£1) and certificate.

*Practical Anatomy—First Year*.—G. S. Levis, first prize (£2) and medal; D. P. Clement, second prize (£1) and certificate. *Second Year*.—P. G. M. Elvery, first prize (£2) and medal; T. A. Buchanan; second prize (£1) and certificate.

*Practice of Medicine*.—R. Bury, first prize (£2) and medal; P. D. Sullivan; second prize (£1) and certificate.

*Practical Histology*.—H. C. Carden, first prize (£2) and medal; D. Adams, second prize (£1) and certificate.

*Practical Chemistry*.—R. H. F. Taaffe, first prize (£2) and medal; F. C. Warren, second prize (£1) and certificate.

*Public Health and Forensic Medicine*.—M. Cohen, first prize (£2) and medal; T. H. Massey, second prize (£1) and certificate.

*Materia Medica*.—F. C. Warren, first prize (£2) and medal; J. B. Kelly, second prize (£1) and certificate.

*Biology*.—J. C. S. Day, first prize (£2) and medal; T. C. Boyd and H. W. White (equal), second prize (£1) and certificate.

*Surgery*.—J. S. Dunne, first prize (£2) and medal; R. Bury and F. Lyburn (equal) second prize (£1) and certificate.

*Midwifery*.—J. S. Dunne, first prize (£2) and medal; R. A. Browne, second prize (£1) and certificate.

*Physiology*.—D. Adams, first prize (£2) and medal; T. Sheehy, second prize (£1) and certificate.

*Chemistry*.—D. P. Clement, first prize (£2) and medal; A. E. S. Martin, second prize (£1) and certificate.

*Pathology*.—L. Lucas, first prize (£2) and medal; P. D. Sullivan, second prize (£1) and certificate.

*Physics*.—A. E. S. Martin, first prize (£2) and medal; W. G. Ridgway, second prize (£1) and certificate.

#### The Tottenham Hospital Dinner.

A FESTIVAL dinner in aid of the funds of the Tottenham Hospital was held at the Savoy Hotel, Strand, on November 2nd, 1904, under the presidency of Lord Burnham, a large and influential company being present. In the course of his remarks from the chair, Lord Burnham sketched the growth of the institution from its foundation, and pointed out the immense work which was being done by the hospital, situated as it was in the midst of a densely-populated portion of North-East London. He referred to one of the cherished treasures of the institution—an autograph letter from the late Empress Augusta—which bore testimony to the splendid work performed by the Tottenham Hospital Sisters in the Franco-German War, nor was the high standard lowered in the present day. All that was now required was further extension of the building. Sir Francis Cory-Wright (chairman of the Hospital Committee) announced that operations would not be delayed much longer, as tenders for the building were to be received shortly. The Secretary (Mr. F. W. Drewett) then read out, amid cheers, the stewards' lists, which amounted to £4,002 10s. Mr. John Langton responded on behalf of the medical staff, and Dr. Percy Kidd proposed the health of the chairman.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES or LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**UNIQUE.**—The coroner has absolute power in the matter, and as the presiding judge of his court he directs the jury as he pleases—occasionally, it happens, but very rarely that the jury returns a verdict contrary to his opinion.

### THE DIMINISHING BIRTH-RATE.

A Neo-Malthusian writes calling our attention to the close connection which he maintains is to be found between the land monopoly and the diminishing birth-rate. In reply we can only say it seems likely that anything that unduly increases the cost of living must necessarily make it more difficult to rear families, and hence to make parents disinclined to procreate children. In making this general admission we express no opinion as to the pros and cons, of so-called land monopoly, and the special laws affecting that class of property and the absence of taxation of ground values are somewhat outside the scope of a medical journal. The diminishing birth-rate, however, is clearly enough a fitting subject for medical discussion. It is, however, highly complex and raises issues that can be adequately dealt with only by a consideration of the social, the medical, the political, the statistical, and the economic circumstances of the case.

**BEDFORD.**—Our advice is to take no further notice of the claim, but should another acrimonious letter be received the correspondence had better be placed in the hands of a solicitor, or referred to the Medical Defence Union, if our correspondent happens to be a member of that useful society.

### FEIGHT OF FEAR ILLNESS.

A Correspondent, referring to our annotation on this subject congratulates us on "this singularly timely article in view of the severe attack of 'funkitis' from which the Baltic Fleet is suffering at the moment"; and suggests that we "should send a specially marked copy of the current number to his majesty the Czar, and another to Admiral Rozhdestvenski, care of Admiral Togo."

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 9th.

**DERMATOLOGICAL SOCIETY OF LONDON** (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

**SOUTH-WEST LONDON MEDICAL SOCIETY** (Bolingbroke Hospital, Wandsworth Common).—9 p.m. Paper:—Dr. W. W. H. Tate: "The Diagnosis and Treatment of Tubal Gestation in the Early Weeks."

**HUNTERIAN SOCIETY** (London Institution, Finsbury Circus, E.C.). 9 p.m. Lecture:—Dr. B. Bradford: "The Treatment of Bright's Disease."

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. E. W. Roughton: "Clinique (Surgical)." 5.15 p.m. Mr. F. C. Wallis: "Injuries to and Diseases of Joints."

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (North-Eastern Fever Hospital, St. Ann's Road, N.).—2.30 p.m. Dr. H. Cuff: "Demonstration on Feveris."

**CENTRAL LONDON THROAT and EAR HOSPITAL** (Gray's Inn Road W.C.).—5 p.m. Demonstration:—Dr. Wylie: "Naso-Pharynx."

THURSDAY, NOVEMBER 10th.

**BRITISH GYNECOLOGICAL SOCIETY** (20 Hanover Square, W.).—8 p.m. Papers:—Dr. Maccaughton-Jones: "Embedded Adnexa. Carcinoma of Fallopian Tube, Hemorrhagic Endometritis."—Dr. B. Fenwick: "Uterine Fibroids associated with Ovarian Disease. Adjourned Discussion on Mr. C. Martin's paper on the Treatment of Severe Protrusion by Extirpation of the Uterus and Vagina."

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos Street, Cavendish Square, W.).—8 p.m. Card Specimens will be shown by Mr. Doyne and Mr. Stephenson. 8.30 p.m. Paper:—Mr. S. Snell: "Intraocular Tumour covering the Optic Disc."

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: "Clinique (Surgical)." 5.15 p.m. Dr. W. Ewart: "The General Management and Special Methods of Treatment of Heart Cases."

**MOUNT VERNON HOSPITAL FOR CONSUMPTION and DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture:—Dr. G. Johnston: "Aortic Aneurysm (illustrated by cases)." (Post-Graduate Course.)

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture:—Mr. H. W. Carson: "Middle-Ear Carcinoma."

FRIDAY, NOVEMBER 11th.

**THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH** (9 Adelphi Terrace, Strand, London, W.C.).—7.30 p.m. Paper:—Dr. G. A. Baron: "Instruction in Hygiene in Universities and Schools—a Proposal."

**BRITISH LARYNGOLOGICAL-RHINOLOGICAL and OTOLOGICAL ASSOCIATION** (Medical Society's Rooms, 11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Council Meeting. 4 p.m. Exhibition of Cases, Specimens, and Instruments. 4.15 p.m. General Meeting. Presidential Address. Dr. Horne: "Pachydermia Laryngis."

**POST SANITARY ASSOCIATION** (Westminster Palace Hotel—11 noon. Meeting.

**CLINICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Paper:—Mr. C. R. Keyser: "A Case of Congenital Elevation of the Scapula."—Dr. P. D. Turner and Mr. E. Johnson: "Traumatic Axillary Aneurysm successfully treated after Extravasation had occurred by Proximal Ligature."—Mr. B. Robinson and Mr. E. M. Corner: "Aneurysm of the Intracranial Part of the Left Internal Carotid caused by a Bullet Wound through the Right Eye."—Mr. S. Page: "A Case of Appendix Abscess followed by Abscess in the Left Iliac Region."

**MEDICAL GRADUATES' COLLEGE and POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Dr. St. Clair Thomson: "Clinique. (Throat.)"

## Vacancies.

**Peckham House Asylum.**—Second Assistant Medical Officer. Salary £150 per annum. Applications to the Resident Licenses, Peckham House, Peckham, S.E.

**Birmingham City Asylum, Rubery Hill, near Birmingham.**—Junior Assistant Medical Officer. Salary £150 per annum, with board &c. Applications to the Medical Superintendent.

**Manchester Jewish Hospital.**—Resident Medical Officer. Salary £20 per annum. Applications to Secretary, Jewish Hospital, Cheetham, Manchester.

**Braecliffe Asylum, near Lincoln.**—Junior Assistant Medical Officer. Salary £126 per annum, with furnished apartments, &c. Applications to W. T. Page, jun., Solicitor and Clerk to the Visiting Committee, 5 Bank Street, Lincoln.

**St. Mary's Hospital, Oxford Street, Manchester.**—House Surgeon and Resident Obstetric Assistant Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary, University of Birmingham (Faculty of Medicine).—Professor of Anatomy. Salary £200 per annum. Applications to Geo. H. Morley Secretary.

**Royal Berkshire Hospital, Reading.**—House Physician. Salary £80 per annum, with board, lodging, and washing. Applications to the secretary.

**Royal Dental Hospital of London, Leicester Square.**—Patron: His Majesty the King.—Dental Superintendent. Salary £250 per annum. Applications to J. Francis Pink, Secretary.

**Fisherton House Asylum, Salisbury.**—Medical Superintendent. Salary £400 per annum, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

**County Asylum, Mickleover, Derby.**—Junior Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

**Leicester Infirmary.**—House Surgeon. Salary £100 per annum, with board, apartments, and washing. Applications to Harry Johnson, House Governor and Secretary, the Infirmary, Leicester.

**Royal Portsmouth Hospital.**—Senior House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to J. S. Neil, Secretary.

**Catholic University of Ireland.**—Joint Professor of Anatomy. Applications to the Registrar of the Medical School. (See Advt.)

## Appointments.

**AARONS, S. JERVOIS, M.D. Edin., M.C.C.P. Lond.,** Pathologist and Curator of the Museum Hospital for Women, Soho Square, W.

**BRADSHAW, THOMAS E., M.D. Dub., F.R.C.P. Lond.,** Examiner in Medicine in the University of London.

**BROCKBANK, F. M., M.D. Vict., M.R.C.P. Lond.,** Junior Physician to the Children's Hospital and Dispensary, Manchester.

**BUCHANAN, P. S., M.B. Glasg.,** in Charge of the Out-door Midwifery Department of the Glasgow Public Dispensary.

**BURNEY, C. D. FRANCIS, M.R.C.S.,** Divisional Surgeon to the E Division Metropolitan Police (Deptford), and also Divisional Surgeon to the police stationed at Deptford Victualling Yard (Woolwich Division).

**COUTTS, E. N., M.B. Toronto, L.R.C.P. & S. Edin.,** Resident Physician to the Royal Infirmary, Glasgow.

## Births.

**BLUMER.**—On November 4th, at St. Mary's Grove, Stafford, the wife of F. Milnes Blumer, M.B., of a son.

## Marriages.

**MACNAMARA—JERMAIN.** On November 5th, at Nazira Assam, India, John Radley Macnamara, F.R.C.S.(I), Medical Officer, Assam Compy, to Natalie Maude, youngest daughter of Captain Jermain, E.N., of the Cottage, Orondall, Hants.

## Deaths.

**ALLINGHAM.** On Nov. 5th, at Marseilles, Herbert W. Allingham, F.R.C.S., of 25 Grosvenor Street, London. Aged 42.

## Original Communications.

### THE VARIOUS PHASES OF A HOSPITAL'S WORK. (a)

By SIR C. J. NIXON, M.D.,

Physician to the Mater Misericordiarum Hospital, Dublin.

AFTER some introductory remarks dealing with the past history of the hospital, and a reference to the loss it had sustained by the death of Mr. Patrick Hayes, its senior surgeon, Sir Christopher Nixon said that it was in regard to the utilisation of the hospital for the purposes of research that his address was especially concerned, and he asked his hearers to bear with him whilst he endeavoured to put forward this claim as strongly as he was able. The progress of hospital work, he continued, in its relation to the prevention and treatment of disease may be said to be slow and uneventful until the time of Lister. It is true that physicians like Addison and Jenner made record discoveries by pursuing cases of disease from the clinical standpoint to the *post-mortem* room, and no doubt many interesting problems in the biology of disease were made clear by these and other observers. But the stimulus to laboratory investigation dates from the discovery of Lister, who utilised to the fullest extent the labours of Pasteur. That discovery was altogether the result of his observations in hospital, for nowhere except in a large general hospital could he have found materials for that method of treatment which has revolutionised not merely surgery, but the medicine of our day. As an illustration of the effect of the Listerian treatment of wounds, I believe I am correct in stating that the mortality after major operations has been reduced from 40 to 3 per cent.

Who can estimate the gain to humanity of the result of this one instance of hospital research work? It is almost entirely to research work undertaken in the laboratory that pathology may be said to have attained its present position. A comparatively few years ago the work of the pathologist was left to the assistant medical officers—indeed, largely to the senior students. There existed, no doubt, in an imperfectly organised form, the machinery for recording notes and compiling facts in connection with the biology of disease, of comparing these with conditions found after death, and for making generalisations from both data. But there were no means of pursuing inquiries into the modes of origin of disease, nor was any attempt made to determine the nature of obscure conditions which could only be investigated by the use of instruments of precision not then employed. In Dublin in 1894 the first step was taken in the United Kingdom to place pathology in its legitimate position. The Royal University, at the instigation of Sir William Thomson and myself, made the regulation that pathology and bacteriology should be made a special subject of the medical curriculum, and, at the same time, a professorship was created in the Medical School of the Catholic

University, and the professor was appointed pathologist to the hospital. Since then the clinical physician and surgeon have had the advantage of his services. Those who are familiar with the work of the clinician can fully appreciate how much it is bound up with that of the pathologist. In many cases not merely does the diagnosis of the existing morbid condition depend upon the report furnished from the laboratory—a report most frequently made as a result of some bacteriological or chemical investigation—but the line of treatment to be pursued is based upon the conditions which this investigation has determined. There is no difficulty in realising why this should be. The physician studies the disease almost exclusively from its biological aspect; the pathologist in addition investigates it, with all the modern instruments of precision at his hand, from the physical, chemical, and bacteriological standpoint. In many, if not most, cases it is impossible to divorce the two methods of observation; hence the clinician and the pathologist may be regarded as the complement of each other. Let me illustrate my meaning by an example. There is frequently considerable difficulty in diagnosticating between two severe forms of anæmia, a profound chlorosis and progressive pernicious anæmia. There are no special signs or symptoms by which the physician can distinguish one from the other, and it is only when the blood has been subjected to a physical and chemical examination that a correct conception of the existing condition can be formed—a conception which carries with it the knowledge of the life or death of the patient.

But the work of the physician and pathologist does not stop here. The case of chlorosis is quite clear. Employing the known remedies, the patient, almost as a matter of certainty, recovers. But quite different is the case of pernicious anæmia, in which the accuracy of the diagnosis is attested by the inevitable death of the patient. Since Addison and Biermer drew attention to the condition in 1867 a great deal has been learned in connection with the disease and with the changes produced by it in the various organs and tissues of the body. But as yet the primary condition which produces the blood change is unknown. We are unable to say whether it is caused by some chemical disturbance which interferes with cell nutrition and so disturbs the uniform composition of the blood, or by some ferment or toxin which affects the vitality of the blood-cells and leads to their excessive destruction. How are these obscure points to be cleared up? As yet every form of treatment of the disease has proved futile because of our ignorance of the primary disturbance of health. It is only by carefully noting each case under observation, observing every sign indicative of functional and organic disturbance, experimenting with medicines that favourably influence the course of the affection, and, above all, employing the physical, chemical, and bacteriological methods of investigation at our disposal that we shall be able to solve the mystery that at present envelopes the origin of the disease. Such a condition is quite as hopeful for solution as was myxœdema but a few years ago. The clinical investigation of this disease led us to recognise a blood state which reduced the patient to almost a condition of imbecility; was capable of being produced by a removal of the thyroid

(a) An Address delivered at the opening of the Winter Session of the Mater Misericordiarum Hospital, Dublin.

gland, whilst further investigation established the identity of the disease with cretinism, the condition represented by those deformed and stunted specimens of humanity which the traveller meets with among the inhabitants of Switzerland and northern Italy. After a certain stage the steps of inquiry passed beyond the domain of the clinical observer, and the work of investigation was undertaken by the chemist and experimental pathologist. The brilliant results obtained by Horsley by removing the thyroid gland in monkeys, and the adoption of a line of treatment suggested by him and Murray of supplying thyroid gland substance to animals and human beings in which the gland was absent is perhaps an instance of as great a triumph of the art of medicine as it is possible to record. Not alone is the cretinoid condition removed in adults, but even cretins, those creatures who seemed so little removed from mere animal existence, became bright and intelligent, and, if treated at an early age, had their bodily growth and normal configuration restored. I dwell upon this condition because it affords an illustration of what the experimental mode of investigation is likely to lead to. It would be altogether beyond the scope of this address to advert at any length to what has been achieved by experimental research, or to state in detail how much mankind owes to it in connection with the treatment of diphtheria, tetanus, rabies, and in the investigations of the various diseases caused by parasitic micro-organisms. It is this method which, in the study of immunity, has led to the artificial production in the blood of those substances, toxins which will, without doubt, protect the individual against the poison of typhoid fever, pneumonia, the deadly tubercle bacillus, and perhaps from that dread disease, cancer. When we consider how many morbid conditions there are in which there is the most intimate knowledge of the functional disturbance and organic changes which exist—where the biological history is carefully compared with the changes noted after death, and where only one link is wanted to explain the disturbed mechanism—one can realise how limited in usefulness would the clinical observer be if he were content merely to register his failures, and make no attempt to solve the riddles that daily present themselves. Let me mention some common instances of disease, the obscurity of whose origin still remains to be solved. We are all familiar with the symptoms and signs of diabetes, of the pathological changes produced by it, but we are yet in absolute ignorance of the initial point of departure from normal function. A similar difficulty presents itself in exophthalmic goitre, every symptom-complex of which has been made the subject of detailed and elaborate investigation. Subtle nervous conditions—like paralysis agitans, chorea, and epilepsy are yet inexplicable as to their mode of origination. We cannot presume to more than theorise upon their etiology. In pneumonia and acute rheumatism we are equally in doubt. We do not know the conditions which in the one disease make the individual a suitable host for the pathogenic micro-organism, whilst in the other we are unable to determine whether a chemical agent or a microbe sets in motion the morbid state. It would be easy to multiply instances of disease, of the common forms of disease, in which we physicians have to play the rôle of empirics as regards treatment, and in which this humiliating position of empiricism must largely predominate until some advanced degree of certainty is reached by an accurate knowledge of the true nature of the morbid condition; but until that time comes I am afraid we must in many cases be content to accept humbly the old definition of a physician, that he is a satisfaction to the mind of a patient. The public are not given, even granting this mental capacity, to analyse the methods of investigation and treatment employed in any case of disease. An individual has some particular ailment, and he wants to get cured of it. There is not much use explaining to him that we are not as

yet certain of the way in which the disturbance of his health is set up, and that his condition can be only dealt with symptomatically. We may talk to him very learnedly, and look more wise than even a physician could really be, but the patient tells you he came to be cured, and he expects you to work a miracle on his behalf. Such an instance is an answer to the distinguished physicist who some days ago addressed the students of a London hospital. He very truly pointed out that the fundamental studies of medicine were of a strictly materialistic nature, that they belonged to a different world from that which constituted the main object of a student of medicine, and that we should not deal with living men and women as if they represented a mere physical mechanism, as mere laboratory or chemical specimens. But, unfortunately, as we know nothing of the problem which constitutes life, we have no other methods of analysis of processes of disease except by noting physical and chemical phenomena, and comparing these in any given case with a normal standard, and that normal standard is one that is conditioned by the principle of life. What is meant to be conveyed by the lesson is that we are not to regard our patients as merely a piece of very fine mechanism, constructed by a skilled artificer, which will not bear rough or unintelligent interference, but as a type of the most supreme specimen of delicate structure endowed with the unknown principle of life, and therefore to be dealt with on a plane apart from ordinary physical and chemical methods of investigation. I venture to consider this line of argument may be considered to be what is known as a *sciomachy*, a battle with a shadow. Where, I ask, is there the slightest ground for believing that a single thought or act in connection with the sufferer in any hospital is not associated with his well-being, and in what instance is there any advance of knowledge that is not utilised for his benefit? In all obscure cases it is our duty to unravel the web, and in doing this by the finite means at our disposal we are steadily pressing onward to the goal which marks the limit of human progress in medicine. It is only in this way we may hope to satisfy those who come to us for relief.

And here I think it my duty to freely acknowledge the thoroughly progressive spirit in which the Sisters of Mercy have administered the affairs of this hospital, their readiness at all times to accede to the recommendations of the Medical Board in all matters which are essential to the welfare of the patients and of the institution generally, and to their never-failing consideration and courtesy towards both the staff and the students.

It was this spirit of progress which impelled those responsible for the management of the hospital to provide the necessary facilities for the carrying on those researches which will lead to our more accurate knowledge of disease and its treatment. They have provided us with a laboratory which, under the direction of the pathologist of the hospital, Professor McWeeney, will be utilised for the progress of the science and art of medicine. Professor McWeeney will be glad to show our visitors over the laboratory and explain to them the points of interest in connection with it. Upon him will rest a great responsibility, the charge of the pathological department of a great hospital, and I will only say of him that I believe him to be intellectually fitted for the post. There is a remarkable point worthy of notice in connection with the pathological department of the hospital. The Royal University grants studentships in two subjects of the medical curriculum—physiology and pathology. The pathological studentship is awarded every alternate year, and since its foundation five studentships have been awarded. Out of these five, four have been gained by former students of the hospital—the first by our own professor, Dr. McWeeney; the second by the distinguished assistant physician of St. Vincent's Hospital, Dr. Dargan; and the third by Dr. Curran, the assistant surgeon to this hospital; and the fourth

by Dr. Denis Farnin. Much, it is hardly necessary to say, is expected from a triumvirate representing such brilliant attainments.

The encouragement given by the managers of the hospital to the employment of scientific methods of investigation of disease necessitated an encroachment upon its slender resources. But the enlightened spirit which provided those facilities for research is bound to have its reward in perfecting our means of combating disease and alleviating human suffering. To me, personally, the opening of a new laboratory is an occasion of extreme interest. I have been connected with the hospital for thirty-six years; I have noticed its steady development and progress, and now, in the forty-third year of its existence, it may be said to be entering upon a new career of usefulness. It has, as you are all aware, an intimate connection with the Catholic University School of Medicine, and I venture to express a hope that the bond between the two institutions will be even more strongly cemented in the future. A great school of medicine—and the Catholic University School, with all its drawbacks as to position, structural proportions, and lack of endowment, can claim to be by far the largest school in Ireland, a distinction which many will regard as of some importance—should be in the closest relation with a great hospital, so that the research work of each would be facilitated and augmented. In this way the tone and status of medicine in Ireland would gradually reach the level of that attained by the great Continental schools. There should be no hesitation in accepting this view. Before the introduction of the modern methods of precision in the diagnosis of disease the Dublin school was, in many instances, in advance of the great schools in Germany, France, and Austria. Graves, Collis, Corrigan, Stokes, and Adams constitute a quintette of original observers, each one of whom is handed down to posterity as the discoverer of the special disease which bears his name. But just as the sister country has fallen so much behind in all scientific work, and as her industries have been to a large extent monopolised by America and Germany, so medicine in Ireland has not held its own in research. Yet it may be asked, is there any quality of brain power in Ireland which, under favourable conditions, would prevent it from successfully competing with that of the Germans or the French? To have signal results I hold you must have a combination of a great hospital with a great school. Given a completely equipped school of medicine, having each department thoroughly organised, manned by a competent staff of professors and assistants, and collaborating its work with a great hospital, which the spirit of the time has made ideal in all its departments, then I do not say I believe, but I feel confident, the genius of Irishmen will make their country a home for scientific progress in medicine. It is scarcely possible to conceive, with the encouragement that is being given to the various conditions bound up with industrial and agricultural life in Ireland, and with such indications as are presented of the dawning of prosperity and progress, that no consideration will be given by the State to a profession from which it extracts so much profit. I say this notwithstanding that the opportunity which was recently afforded to the Government of settling the University question in such a way as would provide a school of medicine commensurate with the requirements of students of the country at large was not, unfortunately, availed of. The report of the Royal Commission on University Education in Ireland appears likely to share the fate of most Royal Commissions, the reports of which, so far as Ireland is concerned, result in vitalising the conditions they were appointed to remedy. It is stated that the present Government has fallen back no less than 34 times on Royal Commissions, at a cost to the country of £392,000. In Ireland we have had several, and in most of them the outcome was uniform—no result. Indeed, in connection with higher education in this

country, one would feel inclined to urge the friends of the University of Dublin to demand the appointment of a Commission to consider the present condition of the higher, general, and technical education available in Ireland inside Trinity College, Dublin. No matter what the Commissioners report, it is almost a certainty that the *status quo* will be maintained, and the University will be able to repeat MacMahon's response at Malakoff—" *J'y suis, j'y reste.*" Still, if a comment may be made upon the recent report on University Education presented to his Majesty, it is not to say that, prepared as we may be for the policy of *laissez faire* which, in regard to Ireland, appears to be a characteristic of our Government, still, one would hope there is a limit which no self-respecting Government would outstep in dealing with a country which it professes to govern, and with a body of men to whom it entrusted an almost sacred mission. The condemnations and recommendations of the Commissioners are so destructive in their nature that in face of them to maintain an institution which, in the words of the Act establishing it, was to promote the advancement of learning in Ireland, appears to be "a mockery, a delusion, and a snare." The three main findings of the Commission were that the Royal University lowered the ideal of University education, that its system of making appointments to the Senate and offices of the University was indefensible, and that the system adopted by it of indirectly endowing certain colleges must be condemned. It is scarcely conceivable that no action would be taken upon this report, coming from a body of experts appointed by practically the same Government which abolished the Queen's University and substituted in its place the Royal University, or that any Government would be so inconsiderate, to say the least, as to continue to impose upon the members of the Senate the duty of administering the affairs of an educational body which was the subject of so strong a censure. Or is its policy to be represented by the lines—

"I see the right, and I approve it, too;  
Condemn the wrong, and yet the wrong pursue" ?

There must be some change effected, and with the change I hope will come the realisation of my ideal—a great and thoroughly equipped school and hospital bound together by the closest bonds of union, and working for the common object, the progress of our profession.

In connection with the question of Commissions, appointed to redress Irish grievances, I should like to advert briefly to one which for the moment excited keen interest amongst the hospital charities of Dublin. In March, 1885, a memorial from the Medical Board of this hospital was presented to the then Lord Lieutenant, Earl Spencer, praying that an inquiry should be held into the conditions, as regards work done, and the management of each hospital in Dublin, with a view to a redistribution of the Parliamentary grant annually voted for the maintenance of some of these hospitals. The prayer of the memorial was acceded to, and in April, 1887, a Commission was appointed to make inquiry into the management and working of the hospitals in the city, the conditions upon which annual grants from the public funds were given for the support of certain hospitals, and whether any redistribution of such annual grants was expedient and advisable. The Commissioners sat for a period extending over some five months, and examined 86 witnesses, from whom valuable information was obtained upon all points in connection with hospital management, none more valuable than that given by my colleague, Mr. Chance, the President of the College of Surgeons. The Commissioners, seven in number, unanimously signed a report which made, amongst others, the following important recommendations:—  
(a) That the annual grant should be commuted for a capital sum, to be invested in the names of trustees, and the interest thereon should be paid to a central

board to be distributed by them to such hospitals as should fulfil certain specified conditions. (b) The conditions laid down to entitle any hospital to a share in the distribution of the grant referred to the number of beds occupied, the number of students attending clinical instruction, the number of nurses and probationers trained, the general efficiency of the institution, and the energy of the directors, as evidenced by the amount of money collected in the shape of private subscriptions, donations, and bequests. I would not be justified in saying that the report gave universal satisfaction, but I believe I am within the strict limits of truth in stating that the feeling which prevailed amongst members of the profession and of the public generally was that a solution eminently fair and practical had been arrived at, and that, with due regard to vested interests, the recommendations of the Commissioners would be given effect to. This view was confirmed by the course taken by the Government of the day, for in August, 1889, a Bill giving effect to all the proposals specified in the report of the Commission was introduced by Mr. Jackson, the Chief Secretary for Ireland for the time being. And now occurred an action of a mysterious nature. For some cryptic reason—there never was the least attempt to explain the why or wherefore—the Bill, after being read a second time, was withdrawn, and the report of the Dublin Hospital Commission shared the fate meted out to the many Commissions which preceded and followed it. I would hardly think it necessary to touch upon this matter but for the dim shadows that are appearing heralding the advent of some fiscal arrangement by which all Irish moneys will be dealt with by a purely Irish Executive. If this should come about, whether by "devolution" or some more advanced and more stable scheme of reform, I should hope the demand for equitable consideration of each hospital in Dublin will be complied with.

I have only to add a few words to the students of what I am justified in calling a national institution. This hospital, if developed on the lines indicated in my address, cannot but be ultimately associated with the progress of medicine in Ireland. It may be that some of those whom I have the pleasure of addressing may play an active part in rendering it a pioneer in the advancement of that knowledge which is essential to the well-being of our race. With the most striking evidences presented to us of the almost illimitable powers of man's productiveness in every department of physical science, especially during the latter half of the century just passed, in which the record of wonders appears to have been reached, it is not likely that the science of medicine will stand still. There are indications that we are moving in the direction of some great discoveries in connection with the prevention and treatment of disease which will be no less startling than those of the physicist and chemist, with this distinction—that whilst they deal with material substances, our lot concerns alone the well-being of our own species—man. Our profession is not one that brings either ease or wealth in its train. To the vast majority of those who embrace it as a calling there is but little beyond a well-earned competence. But with its many drawbacks it has within it elements of human interest which contrast favourably with the sordid and debasing elements of other pursuits. We certainly, in our profession, have a great incentive to live up to Sydney Smith's noble ideal—Let every man be occupied, and occupied in the highest employment of which he is capable, and die with the consciousness that he has done his best.

#### The Royal University of Ireland.

HIS MAJESTY'S Royal Warrants have been received appointing Rt. Hon. Lord Killanin, Sir William Thomson, C.B., M.D., and Dr. Bertram C. A. Windle, President of Queen's College, Cork, to be members of Senate.

## THE STERILISING OF SURGICAL DRESSINGS. (a)

By A. SCOT SKIRVING, M.B., C.M., F.R.C.S. Ed.,  
Assistant Surgeon, Royal Infirmary, Edinburgh.

SOME eighteen months ago, in considering the cause of an operation case becoming septic, Mr. Skirving had investigated the subject of sterilisation of dressings by the ordinary methods in vogue, in particular by the Schimmelbusch-Lautenschläger steriliser and drum. Though much had been written on the subject of sterilising the skin, the hands of the surgeon, catgut ligatures, &c., there was not very much recent literature on the treatment of surgical dressings, and this had led the writer to consider the whole question. Passing from the simple and trustworthy methods of sterilising by boiling and immersion in antiseptic solutions, the most generally used means, that of steam sterilisation, had to be considered. There were three difficulties in sterilising in this way:—First, as to the steam itself; second, the steriliser; and third, the drum. The first of these difficulties, the kind of steam which it was best to employ, was the greatest, involving, as it did, abstruse questions of thermo-dynamics. The following terms were applied to steam:—Steam in equilibrium, steam in motion, steam under pressure, steam not under pressure, saturated steam, and superheated steam. Ambiguity often arose in using the two last expressions. Saturated steam was steam carrying a certain amount of water in suspension, its temperature, of course, depending on the pressure. As long as this steam remained in contact with the water from which it was produced, its temperature was the same as that of the water. Once away from the water, however, its temperature might be raised without altering its pressure, and steam so treated was said to be superheated. If saturated steam were mixed with water at the same temperature, none of the water was evaporated; if superheated steam were employed in the same way some water was evaporated. The greater the extent to which steam was superheated, the more did it assume the properties of a gas. It was important to surgeons to know that saturated steam had far more sterilising power than superheated steam, as Braatz and Esmarch's researches showed. For example, anthrax spores were killed in five minutes by saturated steam at 100°, but survived superheated steam at 110° for thirty minutes, and at 120° for twenty minutes. Now, a number of sterilisers and disinfectors avowedly made use of superheated steam, especially those in which no circulation of steam takes place, and in which steam is admitted externally for warming purposes at a higher pressure and temperature than that in the interior of the apparatus. Further, it was probable that superheating took place accidentally in a fair number of sterilisers in which this was not included—e.g., some small sterilisers with steam only at 100° C., and not under pressure, if preliminary warming of the dressing is carried out before the steam is admitted. To avoid this, fore-warming ought not to be allowed to exceed 60°. As to the question of steam under pressure, but not superheated,

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, November 2nd, 1904.

experiments conclusively proved that its bactericidal power was enormously increased when the pressure was raised. It was, of course, questionable whether laboratory organisms were exactly comparable to those growing in wounds as regards their power of resistance; and it seemed as though different strains of cultivated organisms varied somewhat in their powers of resistance. Next, as to the question of air in sterilisers. Air, as was well known, was a feeble germicide, and it was a serious menace to effective sterilisation if the air in the apparatus was not completely expelled, as when the lower tap was, through carelessness or accident, not opened at the commencement of the operation. He had made a number of experiments on the temperature in the centre of various dressings under different conditions as to time, pressure and packing. These had convinced him that air was often not completely expelled from the sterilisers, there being sometimes a very considerable difference of temperature between the top and bottom dressings after five or six minutes. This was due to the pressure of air, which, being heavier than steam, collected at the foot, and was a bad conductor of heat. Vendors of sterilisers were too apt to omit to supply information on the extreme importance of allowing air to escape at the beginning of sterilisation. In the old Schimmelbusch steriliser, now frequently discarded in favour of its high pressure derivative, this could not happen, and it also had the advantage of providing a continuous current of steam during the whole process. The effect of packing the drums too tightly was very marked; a difference of 20°C. might be obtained by crowding a drum with too much dressing. Turning to drums, the defects of Schimmelbusch's pattern were pointed out. The hinges, shutters and bolts were all drawbacks; the lid soon ceased to fit closely, and the shutter mechanism was imperfect. A drum was then exhibited which the speaker had devised. It had a sliding-on lid, with a deep flange, round the lower part of which a series of large holes was pierced. The dressings were contained in a gauze basket inserted into the drum, the lid was put on, but not thrust home, so that steam entered the drum through the holes in the lid; when sterilisation was over the lid was pushed firmly down, so that this communication was blocked. The bottom of the drum had a small hole, occluded by a screw cap, by which water could be drained off if need be. In using the drum, Mr. Skirving had found that the dressing was much more effectually sterilised when the drum was put into the steriliser upside down, the explanation being that convection of heat then came into play, the hot steam ascending from the entrance holes in the lid, now lowermost, and reaching the top of the dressing much more quickly than it would descend to the bottom when the drum was placed upright, with the holes in the lid at the top. The great point about the drum was that it would preserve dressings sterile for a considerable period, which was not the case with ordinary patterns, as, owing to their complicated construction, they were never hermetically sealed, as Mr. Skirving's pattern practically was. The question of heating by convection was of some importance. In all drums heating of the contents resulted from (1) diffusion of hot steam; (2) conduction of heat. If the steam enters by the bottom, convection is added. Convection, as physicists knew, was the important factor

in heating a given quantity of water to a definite maximum temperature, and this idea might be considered in the vexed question as to whether steam is best admitted to sterilisers from below or from above. His final advice was, purchasers of sterilisers ought to get instructions from the makers, not from intermediate sources. In hospitals the ideal plan was to have a central steriliser managed by a thoroughly competent person. All small sterilisers should have pressure and temperature gauges, which should be tested from time to time. Occasional bacteriological tests should also be made, and the condition of the drums should be supervised.

## THE SPA TREATMENT OF ARTHRITIS DEFORMANS.

By W. BOWEN-DAVIES, L.R.C.P., M.R.C.S.,  
Llandrindod Wells.

I HAVE chosen the term "arthritis deformans" after the German and American schools, as I think it a better name for the disease than the more often used "rheumatoid arthritis" or "rheumatic gout," for in the majority of cases there seems to be very little rheumatism and less gout to do with this condition.

The disease is a different one, and requires a totally different treatment, and it is important that it should be dissociated from rheumatism and gout, for the treatment is quite dissimilar. There are, however, very few patients suffering from "arthritis deformans" who have not at one time or another taken drugs and adopted the diet that would be suitable in rheumatism or gout, such as colchicum or the salicylates, or used a low diet free from meat and alcohol. Now, all this treatment is decidedly detrimental to any patient suffering from arthritis deformans, and cannot be otherwise than harmful.

I happen to have had exceptional opportunities of studying this disease during the last few years, both in hospital and out; this must be my apology for bringing forward a type of disease so common to all of those who practise at spas, for though it does not directly lead to death, it certainly does to the most abject misery and progressive deformity.

I have never quite satisfied myself why this disease is practically confined to the female sex, but there is no doubt that it is common about the menopause, and that it is influenced greatly by uterine and ovarian disturbance. Again, mental shock is a very common cause of the onset of the disease, and any acute disease, not necessarily rheumatic fever, is sometimes followed by it.

Influenza seems specially to cause it. I remember one of the first cases that impressed itself upon my memory; it was a very instructive one. A woman, aged about 30, who had no gouty or rheumatic history, the wife of a farmer in seemingly prosperous circumstances. She had two children when I saw her first, and arthritis deformans had already a good hold of her. Her lassitude was extremely marked, and she had evidently made up her mind for a "sofa" life. Shortly afterwards her husband was suddenly killed, and it was found that his affairs were in a most unsatisfactory state; she was left with her two children without a penny. Her husband's

friends came forward and offered to adopt the two children. This she would not consent to; she said she would not part with them, but would make a home for them in a neighbouring village. This she did, and to gain a livelihood for herself and them she took in washing; most of her time was spent at the wash-tub.

I lost sight of her for three years, when she called on me. I hardly knew her, she looked so well, and the joints had almost recovered their suppleness, the lassitude had disappeared, in fact, the disease was cured.

Now what had caused this wonderful transformation? Undoubtedly the change in her life, the excessive exercise she took daily, the scrubbing and rubbing. She said she felt the pain very much at first, but after a time there was only extreme weakness, which lasted longer, but eventually passed away.

Many lessons are, I think, to be learned from this case, the benefit quickly obtained from the regular exercise and what was, to her, hard work. She told me she took little medicine, except cod-liver oil, of which she partook largely.

*Diet.*—It seems to me important that food should be taken not oftener than three times a day. What may be called "nips" of food or drink are bad, and three times a day is often enough to call upon the deranged digestive organs to act. A little alcohol does good, and may be taken in the form of sound malt liquor, stout preferable, or a light wine, such as Moselle, or a weak old whisky and water, but never between meals. Fats should be partaken of freely, especially milk in any shape or form. Extract of malt is a useful addition to the cod-liver oil. Lightly-cooked eggs are always useful. Fresh butter should be taken freely, at least a quarter of a pound daily. The diet should certainly be generous and nourishing.

As I have said before, plenty of exercise in the open air is absolutely necessary, and the more bracing the atmosphere the better. Every joint should be fully bent and extended each day, the patient should be advised to take long steps in walking, and not to sit on low chairs. Indeed, in one case, I recollect a patient who disregarded this advice, and usually sat on an extremely low drawing-room seat, which allowed the hips and knees to contract, until she could only walk in a sitting posture ever afterwards.

At Llandrindod Wells most cases naturally come under the mineral water treatment, and derive much benefit from the waters and baths. They usually take the waters in this form: The hot saline from three to six tumblers before breakfast, with a fifteen minutes' walk after each, and either the sulphur in five or ten ounce doses, with a twenty minutes' walk after each, between eleven and twelve o'clock, and sometimes between three and six o'clock as well, or the chalybeate three or four wineglassfuls two or three times a day after meals; of course this entails exercise.

The baths are found to be most useful, but never the reclining bath, always in the form of needle spray sulphur baths, or what we have found most useful in this complaint, some form of hot air bath, very hot. It is common advice to avoid cold and damp, and in all these cases, no doubt, this is very good advice, but patients often make this an excuse for not venturing out of the house at all, excepting in the finest weather.

Something has been said about the contagiousness of arthritis deformans. All I can say is, that in my experience of thirty-four years, and nearly a thousand cases of this disease, I have only twice seen two members of the same family affected with it, and could not make out any family history of the disease. I have never come across any cases that would give me any reason to consider that the disease in any way has been spread by contagion, nor, in my opinion, is it hereditary. One curious point has been observed, namely, that during the active progress of the disease the evening temperature continues about 99° or 100°, and never much higher.

The pulse, too, is usually found to be about 100; this continues for years, and is itself a valuable diagnostic sign. The extreme lassitude and want of energy which are so marked in these cases is also a valuable sign which seems always to be benefited by prolonged and active exercise in the bracing air. The cure seems a painful one, but is attended by wonderful results, if used diligently before the disease becomes incurable.

There is no doubt that few diseases are more curable, if this is persevered with when the disease is in an early stage.

### Clinical Records.

#### A CASE OF TRICUSPID INCOMPETENCY.

By S. J. Ross, M.D.

THE patient is a man, *æt.* 53, who for the past nine years has had a winter cough. There is no history of rheumatism or any other illness.

Four years ago he noticed that his cough was more troublesome, and his ankles began to swell towards the evening. He had marked dyspnoea. Two years ago when I first saw him his condition was as follows:—Marked cyanosis of lips and cheeks, chest barrel-shaped, lungs markedly emphysematous and *râles* to be heard all over the chest. Cardiac dulness masked by emphysematous lung. Epigastric pulsation very marked. No murmur to be heard; heart's action very irregular. *Pulse.*—100, very small, very irregular. Liver dulness depressed and increased, spleen enlarged. Urine, *sp. gr.* 1030, acid, albuminous; ankles very oedematous.

Steadily his condition became worse, and signs of cardiac dilatation became more marked. A limited soft systolic murmur is to be heard in the tricuspid area.

Hepatic pulsation very marked. Venous pulsation in the veins of the neck, the expansion being synchronous with systole, collapse with diastole. During attacks of coughing the veins attain an enormous size. All his organs were congested. *Lungs.*—Cough very troublesome, with slight hæmoptysis. *Liver.*—Pulsating, slight jaundice; hæmorrhoids. *Kidneys.*—Urine greatly diminished in quantity, of high specific gravity, and almost solid with albumen; spleen enlarged. *Stomach.*—Vomiting frequent, and occasional traces of blood in the vomited matter. Extremities of anterior abdominal wall oedematous. Ascites very marked. *Brain.*—Irritable, and insomnia a troublesome symptom.

*Treatment.*—With rest in bed and an exclusively milk diet, together with the administration of digitalis, the condition of the patient

rapidly improved. When digitalis was rejected strophanthus was retained, which acted equally efficiently, but more slowly. The improvement was so marked that the patient insisted upon getting up after ten days' treatment, and having a less restricted diet, which, of course, invariably ends in a relapse. During one of these relapses digitalis failed to act, the urine steadily decreased in quantity. Caffeine citrate with sodium benzoate was tried, and acted rapidly and efficiently, the urine, which had dropped to twelve ounces in twenty-four hours, after forty-eight hours' treatment rose to forty-eight ounces. For the insomnia trional and paraldehyde were successfully employed; the former drug requires watching, as cases are recorded in which its employment has induced acute nephritis. Ten grains at bed-time appears an efficient dose. Hypodermic injections of strychnine were from time to time necessary.

There was no change in the condition of the patient until three hours before death, which took place on June 28th. Then cerebral Cheyne-Stokes respiration appeared, in which there was sudden arrest and sudden return of respiratory movement. Cyanosis became very marked. The patient lapsed into coma and died.

*Remarks.*—The cause of the patient's heart condition was doubtless primarily pulmonary emphysema, so that the tricuspid incompetency was caused by a dilatation of the tricuspid orifice associated with failing compensation, rather than a true valvulitis. At no period of the illness was there any fever. The strictly limited area over which the murmur could be heard is worthy of note. The marked benefit resulting from rest and the administration of digitalis was very striking in this case.

## British Health Resorts.

### XVI.—BATH.

It is claimed that the virtues of the thermal springs, on which in great measure depends the reputation of Bath, were known in pre-Roman days. It is certain that during the Roman occupation of Britain Bath gained great distinction as a health station. During the eighteenth century it became a resort for the fashionable faddist; but of late years the place has been developed on sound rational lines, and the baths and waters can now be employed with something like scientific precision. (a)

Bath now occupies a foremost place among British spas. (b)

The hot springs which give Bath its unique value appear to have their source beneath the new red sandstone and lias in the palæozoic rocks. Meteorological observations have been regularly made at the stations equipped by the Corporation, and also at the Bath Royal Literary and Scientific Institution. (c)

The mean temperature for last year was 50.2°; the mean daily range, 13.3°; the humidity, 78; the total rainfall, 42.57 inches; and the total duration of bright sunshine, 1,378 hours. The thermal waters are derived from three springs—the Hot Bath of 120° F.; the King's Bath of 114° F.; and the Cross Bath of 104° F. In chemical constitution they are all similar. Calcium sulphate forms the most plentiful ingredient, varying from 80 to 100 grains per gallon. The total mineral matters are from 140 to 165 grains per gallon.

Local enterprise has now provided perfect arrange-

ments for the comfort and convenience of visitors. The Grand Pump Room, Roman promenade, and various baths are in every way excellent. All forms of hydro-pathic treatment are provided, and skilled attendants are always at hand to see that medical orders are fully and scientifically carried out.

The Bath waters can be used externally, taken internally, or, as is generally the case, employed in both forms. Therapeutically, Bath is of greatest service in cases of gout and gouty derangements of all kinds, rheumatism in its chronic forms, and in the remnants of disorder left by an acute attack, osteo-arthritis in some of its less progressive varieties; in muscular and arthritic derangements, such as lumbago, gonorrhœal and some other forms of arthritis; in sciatica and some cases of neuralgia, and chronic neuritis; in certain cutaneous affections, such as eczema, acne, psoriasis, senile prurigo, and particularly akin lesions due to constitutional disorder. In some cases of nervous deterioration, derangement of digestion, gouty respiratory affections, and some diseases peculiar to women, a course at Bath will often accomplish much.

Bath should not be advocated for patients with any form of acute disorder. Tuberculous cases usually do ill. It is not a good resort for "surgical" cases. Epileptics are said to gain no benefit. Marked cardiac disease and aneurysm or other vascular affections are to be regarded as contra-indications. Bath offers many attractions to the aged and the invalid who desires a quiet yet not altogether retired life, where while in the world he may not necessarily be of the world. The city is, moreover, well provided with hotels of all kinds, and excellent apartments can always be obtained. Bath is 107 miles from London, and can be readily reached by the Great Western Railway in a little over two hours.

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.  
MEETING HELD NOVEMBER 11TH, 1904.

The President, DR. TAYLOR, in the Chair.

MR. C. R. KEYSER narrated the case of a girl, æt. 9, who was admitted into hospital in December, 1903, with a Congenital Elevation of the Scapula. The deformity had been noticed for one month only. There was no history of injury, and no similar case was known in the family. The left shoulder was 2½ inches higher than the right; there was no osseous ridge connecting it to the spine. The third dorsal vertebra was prominent and displaced slightly to the left. There was no paralysis of the arm or of any local muscle. Evidences of slight rickets were present. Cases of this class were rare, and fell into four groups: (1) Those having an osseous ridge joining the scapula to the spine; (2) those with absence of one or more muscles of the shoulder or girdle; (3) those with a long, everted, supra-spinous portion of the scapula; (4) those in which the scapula was small, but in which no other abnormality of bone or muscle was present. This group comprised most of the cases. The affection was usually unilateral, and occurred more frequently on the left side. Other deformities, such as spina rigida, were often present. Sprengel's theory as to the pathology of the condition was that the arm was misplaced behind the back *in utero*. The formation of the bony ridge, which was present in some of the cases, was discussed, and references made to other recorded examples of the deformity.

MR. RUPERT BUCKNALL had seen an exactly similar case, and several cases closely resembling the one described. The bulk of evidence was against the condition being an acquired one or, as Sprengel thought, due to malposition *in utero*. If the latter theory were true, one would expect to get deformity of the arm and hand. The question of the osseous ridge was a very interesting one. He thought that it was probably not of supra-scapular origin, for if the muscles were carefully examined, whether they were shortened, fibroid,

(a) See article by the late Dr. W. M. Ord and Dr A. E. Garrod, in "Climates and Baths of Great Britain." Vol. I. 1895.

(b) See "Medical Guide to the Hot Mineral Baths of Bath." 1901.

(c) "Thirty-eighth Annual Report of the Medical Officer of Health," by Dr. W. H. Symons. 1904.

or bony, their condition always accurately accounted for the position of the scapula, that being sometimes elevation, sometimes rotation, and sometimes adduction. If the rhomboids were affected, adduction occurred; if the trapezium, elevation. Often the osseous ridge did not accurately correspond with the muscle, *i.e.*, it was not confined to one given muscle. This fact had been read as indicating that the change occurred in very early life, before differentiation of the muscles had taken place. This theory also was in line with the presence, in these cases, of deformities in the spine and elsewhere.

Mr. KEYSER said that the presence of cartilage between the scapula and spine did not fit in with the primary muscular defect theory.

Dr. PHILIP TURNER and Mr. RAYMOND JOHNSON described a case of Traumatic Axillary Aneurysm, in which, after extensive extravasation had occurred, a successful result was obtained by the application of a ligature to the axillary artery in the first part of its course. The patient, a woman, *æt.* 70, fell downstairs on to the left shoulder, the injury being followed by much bruising of the part and paralysis of the hand and forearm. Three weeks later, it was found that a pulsating tumour as large as a tangerine orange was present in the anterior part of the axilla; the pulse at the wrist was not perceptible. After the lapse of several months great improvement had occurred in the muscular power, and the radial pulse was again perceptible. During the third year after the accident, some gradual increase was noticeable in the size of the aneurysm, without, however, any symptoms of pressure. Nearly three years after the onset, a small bruise appeared over the posterior axillary fold; and a few days later a considerable extravasation occurred, with intense pain and extensive discoloration of the skin. The axillary artery was tied in the first part of its course. On the morning of the operation, it was found that blood was just beginning to leak through a small opening which had formed spontaneously in the discoloured skin. All pulsation in the axilla was arrested by the ligature, but no anxiety was at any time felt as to the vitality of the limb, the circulation in which remained good. The opening in the skin of the axilla continued to discharge slightly until about three weeks after the operation, when a very free escape of the extravasated blood occurred, and after slightly enlarging the opening a quantity of coagulum was removed. From this time the discharge quickly lessened, the swelling gradually and completely subsided, and the final result was in every respect satisfactory. It was pointed out that the chief practical interest of the case consisted in the fact that a traumatic axillary aneurysm, after the occurrence of extensive extravasation, was successfully dealt with by the proximal ligature. According to the usual teaching on this subject such a favourable result was hardly to be expected in such circumstances and at such an age. Probably the long duration of the aneurysm had a favourable effect, by causing the collateral supply to be well established. The treatment adopted was far less severe than the alternative method of freely opening up the axilla and dealing with the artery at the site of the aneurysm. Reference was made to certain cases recorded by Major Birt, of traumatic aneurysm from bullet-wounds, in which the treatment by proximal ligature was adopted with success. In two cases of diffused extravasation into the axilla a successful result followed ligature of the subclavian artery in the third part of its course.

Mr. H. BETHAM ROBINSON and Mr. EDRED CORNER narrated a case of Aneurysm of the Intracranial Part of the Left Internal Carotid Artery, caused by a bullet wound through the right eye entering about the right outer canthus and completely destroying the globe. There was no wound of exit. When admitted into St. Thomas's Hospital immediately after the accident, the patient was unconscious and showed signs of cerebral irritation. The right eye was at once excised. On the seventh day the left eye was suffused and the cornea dull; on the eleventh day there was severe

epistaxis, controlled by plugging the nares; and on the thirteenth another, more severe. The cornea ulcerated, and on the twenty-fourth day sensation was absent over nearly all the distribution of the upper two divisions of the fifth nerve; ptosis and paralysis of the sixth nerve occurred; complete ophthalmoplegia externa occurred on the thirty-third day. After several attacks of hæmorrhage, which always came from the right nostril, the same side as the destroyed eye, Mr. Corner ligatured the internal and external carotids on the right side. On the sixth day after this she woke up completely blind, this being thought to be due to some lesion of the optic nerve behind the entrance of the central vessels. There was a transient hemiplegia on the left side. From now onwards there was no further hæmorrhage, and her general condition gradually improved, the partial paralysis passed off, and consciousness returned. On the 195th day she was sent to a convalescent home, being quite well, no bleeding having occurred since the 118th day. This period of improvement lasted for another twenty days. She was then readmitted for another severe hæmorrhage from the right nostril, which was stopped by plugging. Three days later a very violent hæmorrhage occurred, and she died in three minutes. At the autopsy the bullet was found to have pierced the inner wall of the right orbit, traversed the body of the sphenoid, and entered the interior of the skull close to the left anterior clinoid process. From this point it had turned backwards and lodged on the under surface of the brain close to the calcarine fissure. A splinter of bullet had branched to the left and lodged in the under surface of the hinder part of the temporo-sphenoidal lobe. Close to the anterior clinoid process was a small aneurysm of the left internal carotid artery, and lodged in its wall was a splinter of bone. The sac communicated with the track of the bullet, and so with the right side of the nose, along which the fatal bleeding had taken place.

Mr. STEPHEN PAGET described the case of a girl, *æt.* 13, whom he operated on for Acute Appendicular Abscess. Five ounces of thick, foetid pus were evacuated. Nine days afterwards another abscess appeared in the left iliac region between the bladder and rectum, and a pint of pus was again evacuated. The patient, after recovery, complained on several occasions of colicky pain in the abdomen. Fifteen months later, she was seized with severe pain and vomiting. The abdomen was opened and a coil of gut was found to be nipped by an adhesion which extended transversely across the abdomen. From this operation the child made a perfect recovery. Stress was laid on the following points:—The appendix was removed at the first operation, so that the extension of suppuration to the left iliac region was not due to a septic appendix having been left in the wound. The intermittent pains that followed the earlier operations were accompanied by nocturnal epilepsy, which perhaps caused the gut to get caught by the adhesion. These pains were vaguely attributed to stretched adhesions, and their true significance not realised. After double suppuration in the abdomen, acute intestinal obstruction was likely to be caused by an adhesion between the two foci and not at either. No epileptic fits occurred while the wounds were open, but began as soon as these healed.

Dr. FRENCH asked whether it was the rule for the fits to cease in epilepsy while operation wounds were present. Perhaps anti-epileptic treatment was being carried out more vigorously at this time.

Dr. PASTEUR inquired as to the frequency of adhesions after abdominal operations.

Mr. MCGAVIN said that the question of post-operative adhesions was a very important one. They might be expected to occur after an acute inflammatory condition such as that present in Mr. Paget's case. He referred to a case in which laparotomy was done for tuberculous peritonitis and no adhesions found. Later, acute intestinal obstruction occurred, and the child died, the parents refusing operation.

Mr. R. P. ROWLANDS described a similar occurrence many years after an ovariectomy.

Mr. ZUM-BUSCH had operated on many cases of ventral hernia consequent on appendix operations.

Mr. PAGET stated that no bromide had been administered to the child during her stay in hospital, as the epilepsy was only discovered shortly before her discharge. He remarked on the great variations in the number of adhesions that occurred in different patients, instancing the occasional cases of extreme and fatal prolapse through colotomy wounds as evidence that sometimes no adhesions at all were present.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.  
MEETING HELD NOVEMBER 2ND, 1904.

PROFESSOR JOHN CHIENE, President, in the Chair.

MR. C. W. CATHCART showed (1) a patient after operation for fæcal fistula; and (2) a case of scirrhus erythema after removal of both mammae for scirrhus.

MR. ALEXIS THOMSON showed (1) a boy, æt. 15, after nephropexy for floating right kidney. The youth of the patient was commented on as unusual. (2) A woman, æt. 27, after conservative operation for hydro-nephrosis. The kidney was displaced down, and the ureter, though not kinked, did not, on account of the level at which it entered the kidney, drain the pelvis of the organ properly. There was a large sacculcation below the exit of the ureter. The treatment consisted in raising the kidney, and fixing it in its normal position, so that the ureter drained the most dependent part of the pelvis. (3) A case of popliteal aneurysm treated by excision of the sac after distal ligation; though it relieved the symptoms, this had failed to cure by causing coagulation in the sac.

DR. G. A. GIBSON showed a specimen of sarcoma of the root of the left lung involving the pericardium.

MR. SCOT SKIRVING showed a drum for sterilising and storing dressings.

MR. SCOT SKIRVING read a paper, entitled

QUESTIONS REGARDING THE STERILISING OF  
DRESSINGS,

a full abstract of which will be found on page 512.

The paper was discussed by Messrs. Macgillivray, Cathcart, Caird, and Dr. Littlejohn.

DR. MELVILLE DUNLOP read a paper on

SYPHILITIC SYNOVITIS IN CHILDREN.

The condition was one deserving of wider recognition than it had generally received, and was much more frequent than was usually supposed. After a brief reference to the literature of the subject, the speaker said that syphilitic arthritis was very often confused with other forms of chronic joint disease, but that it was of great importance to recognise its true character, as otherwise it was very likely to be treated, unsuccessfully, as if it were tuberculous. It might occur either in acquired or hereditary syphilis, but was much more common in the latter. Sometimes an acute synovitis was met with before the eruption appeared; gummata of the joints had been described, chiefly as secondary to gummata in the adjacent bone, this form being liable to confusion with sarcoma. All these, however, were rare in childhood. The common forms of syphilitic synovitis in children were two in number—(1) synovitis secondary to syphilitic epiphysitis in infants, due to extension of the mischief from the epiphysial line. In these cases there was first the epiphysitis running on, sometimes, to separation of the end of the bone, with degenerative changes in the articular cartilages. If suppuration occurred it was due to a secondary infection, not to syphilis alone; the pus might invade the articulation, causing an abscess in the joint. The condition usually developed rapidly during the first three months of life. It affected the arms, and particularly the distal joints, in preference to the legs, was usually symmetrical, one side, however, being worse than the other. On examination, swelling could be felt in the neighbourhood of the epiphysis, the joint contained a little fluid, tenderness might be present or absent, and powerlessness of the limb—syphilitic pseudo-paralysis—was an almost constant

accompaniment. When separation of the epiphysis occurred, there was unnatural mobility; crepitus, however, was rare. The prognosis was good as to restitution of the function of the limb; shortening did not tend to occur, and suppuration was rare. Two illustrative cases were briefly recorded. (2) True primary chronic syphilitic synovitis.—This was a late tertiary manifestation, it was very insidious, and was often discovered accidentally. The disease usually occurred in children, æt. between 8 and 15, at the age at which interstitial keratitis was frequent. The arthritis was very symmetrical, and of all joints the knees were most likely to be involved, the ankles and elbows much less commonly, while no instance of affection of the shoulders or hips had been recorded. The disease did not attack the two joints simultaneously, but at an interval varying from two or three weeks to several years. In this respect, in its favourable course, and in its date of onset, it presented certain resemblances to interstitial keratitis, with which, as a matter of fact, it was not uncommonly associated, and it was to the ophthalmologists that some credit was due in the recognition and recording of the affection. Generally speaking, one joint was more severely affected than its neighbour. The onset was very gradual and quite painless, and, except for some stiffness, the function of the limb was not interfered with. In consequence of the latency of the symptoms, the condition was, therefore, very liable to escape the notice of unobservant patients. On examining the joint a swelling was found, due entirely to synovial effusion, with sometimes slight thickening of the synovial membrane. There was no redness, no starting pains at night, no creaking, and no pain or tenderness; only slight loss of mobility. It had been stated that as many as 75 per cent. of cases of keratitis showed some degree of this joint lesion. The other stigmata of syphilis—Hutchinson's teeth and deafness—might be present; nodes were particularly frequent. The condition was by no means uncommon; Dr. Dunlop had met with some sixteen cases. Relapses were very liable to take place. Little was known as to the pathological changes, as the cases were seldom fatal. On the whole they seemed to be slight—a little hyperæmia of the synovial membrane, some thickening of the fingers in some cases, sometimes villous outgrowths developed in the synovial pouches, in one or two instances small gummata had been present. The diagnosis rested on the bilateral symmetry of the arthritis, the insidious onset, absence of pain, and slight loss of function. As to the treatment, although not all cases responded to anti-syphilitic remedies, the disease was usually very amenable to mercury and potassium iodide. Several cases illustrating the various points raised were reported.

DR. CHALMERS WATSON gave a communication, of which the following is a very brief *résumé*, illustrated by a lantern demonstration, on

GOUT: OUR PRESENT POSITION WITH REGARD TO ITS  
ETIOLOGY.

All our views of gout, he remarked, were coloured by the influence of Garrod's teaching that uric acid is the primary factor in the disease, and this theory has been almost universally accepted, e.g., by Ebstein, von Noorden, Roberts, and others. Of late years, however, this view has been questioned by clinicians, among whom Goodhart's name might be mentioned. The author's investigations had led him to abandon the view that uric acid was an important etiological factor, the steps leading to this being, shortly, as follows:—

A. *Chemical*.—Uric acid was found in the blood in a number of diseases having no known relationship to gout, thus confirming the work of previous observers. In leucocythæmia, for instance, uric acid was present in quantities far exceeding that found in gout, and it was impossible to imagine that if the uric acid acted as a poison its action should not be greater, the more there was of it in the tissues. Further, an analysis of the urine in acute gout showed no disturbance of the

uric acid secretion, either before, during, or after the paroxysm; and the same results were got in the administration of nucleins to gouty persons.

**B. Histological.**—The morbid appearances observed in gout in the lower animals and chronic gout in man do not support the uric acid theory, but rather suggest an infective condition. After removing urates from a gouty joint remarkable hyaline structures are seen in the position occupied by the crystals. There seemed no more reason for ascribing gout to the presence of the crystals than to the presence of these hyaline structures. In these, by special stains, Dr. Watson had demonstrated masses of rods, apparently micro-organisms. He was of opinion that the uratic crystals gave the general inflammatory condition of the gouty tissues its specific character, but were not otherwise essential features of it.

**C. Clinical.**—The features of an acute attack—the manner of onset, temperature curve, and blood changes indicative of a disturbance of the marrow function—all suggested the operations of an infective agent. The general conclusions arrived at were that uric acid is not an important etiological factor in the production of gout. This should be considered in relation to the recent views of Woods Hutchinson, Poynton, and Gore. There is an infective element in the disease, and the uric acid gives to the inflammation its specific character. According to this view the source of infection is the alimentary tract, and an injudicious dietary—meat or drink—acts mainly in virtue of its influence on the bacteria normally present in the digestive tract. Reference was also made to the likely times for fruitful investigations, an inquiry into the state of the blood and marrow being suggested as not unlikely to throw fresh light on the disease.

Dr. GULLAND was not inclined to accept Dr. Watson's thesis as proved, and did not consider that he had by any means overthrown the uric acid theory.

Dr. TAYLOR thought that influence of the nervous system in producing gout must be taken into account.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD FRIDAY, NOVEMBER 4TH, 1904.  
The President, Mr. ARTHUR CHANCE, in the Chair.

#### EXHIBITS.

Mr. KENNEDY exhibited a patient after nephrectomy, and the diseased kidney which had been removed; also cases of excision of the knee- and elbow-joints.

Mr. EDWARD H. TAYLOR exhibited a man, *æt.* 39, whose left lower extremity he had amputated through the hip-joint for an osteo-sarcoma of the femur; (2) specimens of rectal cancer removed by the trans-sacral and by the combined sacro-abdominal method; also (3) some unusual forms of urinary (bladder) calculi.

Mr. R. J. MONTGOMERY exhibited a patient showing the result of operation for ectropion of both lower eyelids.

Sir THOMAS MYLES exhibited (1) some recent cases of gastro-jejunostomy; (2) carcinomatous and tuberculous kidneys removed by nephrectomy; and (3) a large fibroma removed from the region of the lesser peritoneal sac.

Mr. W. S. HAUGHTON exhibited (1) case of omento-hepatopexy; (2) case of excision of astragalus for dislocation of thirteen months' standing; (3) case showing new method of "screwing" fractured olecranon.

Mr. MAUNSELL exhibited (1) examples of different forms of goitre; and (2) some pathological vermiform appendices.

Mr. J. B. STORY exhibited an improved mask to exclude buccal microbes from operation wounds.

Mr. SETON PRINGLE exhibited an ano-coccygeal tumour.

Mr. A. B. MITCHELL (Belfast) exhibited a specimen showing the condition of parts after gastro-jejunostomy, followed subsequently by jejunostomy for the relief of regurgitant vomiting.

Mr. A. B. MITCHELL (Belfast) read a paper entitled

"Inefficient Operations for Gastric Ulcer." The paper was based on the results of four different operations, which gave relief for a time, but in all of which the symptoms subsequently recurred.

*Case I.*—A small ulcer on the anterior wall of the stomach was freely excised. Recovery was rapid, and for about a year the patient remained in excellent health; then the old pain recurred, and though some relief was obtained from drugs and diet, her condition was far from satisfactory.

*Case II.*—A large ulcer, which had existed for about twelve years, was infolded by a row of continuous sutures which extended four-fifths round the stomach. The immediate result was all that could be desired, but about eighteen months after operation the symptoms returned, and the patient was soon as bad as ever. A posterior gastro-jejunostomy gave complete and probably permanent relief. The relapse was due to the development of another ulcer higher up in the stomach, all trace of the former ulcer having disappeared.

*Case III.*—A case of well-marked hour-glass stomach had been treated by gastro-gastrostomy. The patient, who had been a chronic invalid for over twenty years, was promptly restored to health and she remained well for one year, then relapsed. Perforation occurred, and she was operated upon and recovered, and finally a gastro-jejunostomy was done in order to afford permanent relief.

*Case IV.*—A gastro-duodenostomy was done for relief of long-standing stomach trouble. The immediate result was most satisfactory, but as the symptoms relapsed in about eighteen months, a posterior gastro-jejunostomy was performed with good result.

These cases were placed on record because a true account of unsuccessful operations is essential to a scientific estimate of the best line of surgical treatment. Mr. MITCHELL expressed the opinion that permanent relief could not be secured except by an operation that did away with the action of the pyloric sphincter, and secured prolonged drainage of the stomach. He now always performed posterior gastro-jejunostomy. He related two cases of regurgitant vomiting. In the first an anastomosis between the ascending and descending loops of jejunum was made, but the result was very disappointing. The patient recovered well from the operation, but got no relief from the vomiting, and died of exhaustion. (Specimen shown.) In the second the bowel was divided, and a Y-operation performed. The result was entirely satisfactory.

Sir THOMAS MYLES stated that his experience of gastro-jejunostomy for gastric ulcer was small, but he had performed the operation for other conditions, such as pyloric obstruction and malignant disease. He thought it would be a matter of considerable interest in cases where gastro-jejunostomy had been performed for the relief of gastric ulceration with hyperchlorhydria to ascertain the condition of digestion afterwards. For regurgitant vomiting he found relief was usually afforded by propping the patient up in bed. He had never found it necessary to perform a second operation after gastro-jejunostomy, and had operated in sixty-one cases without a death. In order to prevent a spur forming at the site of the gastro-intestinal junction he usually sutured the jejunum along nearly the entire length of the posterior wall of the stomach.

Mr. MITCHELL, in reply, stated that experience had led him to prefer gastro-jejunostomy to other operations in cases of gastric ulcer. With regard to regurgitant vomiting, he had observed that when gastro-jejunostomy was done for pyloric obstruction there was never any trouble in this respect, and latterly, when performing gastro-jejunostomy, he had been in the habit of puckering in the pylorus with three or four sutures, thus doing away with the action of the pyloric sphincter, and these cases were amongst the most satisfactory which he had had.

Mr. W. S. HAUGHTON read a paper entitled:—  
THE HEALING OF WOUNDS: ASEPTIC *v.* ANTI-SEPTIC METHODS.

Mr. Haughton, after paying a tribute to the greatness

of Lister's discovery, said that aseptic *technique* was the natural outcome of the principles of Listerism. There was no antagonism between antiseptic and aseptic methods, when properly used—*i.e.*, to reinforce each other when special circumstances required. But there was considerable antagonism between the so-called schools arising from the different value each school attributed to the power of chemical germicides and ordinary cleanliness. His opinion of the leading features of the aseptic surgeon were his appreciation of real cleanliness, his capacity for cleansing and sterilising his operation environment; his ability to maintain the aseptic chain unbroken in a long operation; and his "abstinence" (to use Kocher's own word) from touching sepsis between operations by using rubber gloves for all septic dressings, &c. He then gave Professor Kocher's classification of the channels of wound infection—*vis.*, through air, contact, inoculation, implantation, wound necrosis, and incubation, describing how each might be prevented, and the full details of this *technique* by which they were prevented. Speaking of skin disinfection, Mr. Haughton gave the results of his own experiments from time to time, the latest being done for him by Dr. Earl, which corroborated those of Kocher, Ahlfeld, Needham Green and others—setting great value on the hot-water-dilute-alcohol method (75-80 per cent.), which was equal, if not superior to, hot-water-sublimate methods, and probably also gave a longer period of safety by hardening the skin. Mr. Haughton advocated rubber gloves in all operations—aseptic and septic—as ligatures were freely infected by drawing them tight across the skin of the operator's fingers, and emphasised their value between operations, in dressing or examining septic or mucous surfaces. He further stated that more purely aseptic *technique* in his own practice gave more ideal healing of wounds. While primary union and absence of fever were the rule in his antiseptic days, they were still the rule in his aseptic *technique*; but in addition there was an almost complete absence of pain, even in the most extensive procedures, more rapid healing, which was also firmer and developed less fibrous tissue. Furthermore, in accidental wounds, such as compound fractures and lacerated contused wounds, he attained a higher percentage of aseptic healing when these were only treated by scrupulous and prolonged cleansing, using normal warm saline solution instead of any antiseptic germicide. In conclusion, he said the less one relied on chemical germicides, and more on prolonged cleansing, sterilisation by boiling, and warm normal saline solution, the more satisfactory were the results both to patient and surgeon.

Mr. LENTAINÉ said that as to the definition of aseptic and antiseptic surgery, he understood aseptic surgery to mean where nothing went into the wound in the shape of an antiseptic, chemical or otherwise, and antiseptic surgery, where septic processes in wounds had to be fought by the aid of chemical antiseptics. He considered it a matter of impossibility in general surgical practice to avoid occasional contact with sepsis, and accordingly he did not consider one could rely solely on aseptic measures.

Mr. TOBIN thought the ideal condition of things would be that in which all surgeons used the same methods. It would be well, too, if surgical nurses were all trained on similar lines. He did not think the danger likely to follow from puncture of rubber gloves during an operation very great.

Professor BENNETT agreed with Mr. Haughton as to the advantage of using alcohol as a final disinfectant in cleansing one's hands and the surroundings of a wound. He had found, however, that alcohol applied to the skin of his arms produced severe urticaria; he had found no unpleasant consequences from employing it for his hands.

Colonel McNece, R.A.M.C., Sir Thomas Myles, Mr. Wheeler and Dr. Earl also discussed the paper.

In reply, Mr. HAUGHTON thought that abstinence from sepsis should be the constant aim of the aseptic surgeon, and the best way to do this was by wearing

rubber gloves when dealing with septic cases of all kinds. In the treatment of actually septic wounds he thought weak antiseptics were better than those of greater strength, as the latter acted injuriously upon the tissues. He considered alcohol at a strength of 70 per cent. was better than full strength when employed for the hands. He thought silk was an absolutely satisfactory ligature material for burying in wounds, if No. 1 were used. At the conclusion of his paper Mr. Haughton showed a series of lantern slides illustrating various points in aseptic *technique*.

LIVERPOOL MEDICAL INSTITUTION.  
MEETING HELD NOVEMBER 3RD, 1904.

DR. JAMES BARR, President, in the Chair.

DR. GROSSMAN demonstrated a case of "double congenital anophthalmos" in an otherwise well-developed child, eight months old. The lids were well-formed, though only half an inch in length, and the conjunctival sac was a narrow funnel barely half an inch deep. In the inner half of the right lower lid, a bluish subcutaneous cyst, about half an inch in diameter, was very conspicuous, a so-called coloboma cyst. No trace of a rudimentary eye-ball was to be felt, or seen. This was the third case of the same nature shown by Dr. Grossman before the Institution within the last four years.

AN IMPROVED INHALER FOR ETHYL CHLORIDE.

DR. STENHOUSE WILLIAMS exhibited an inhaler for the administration of ethyl chloride. The apparatus was so constructed that the bottle containing the ethyl chloride is held in position over a tube with a stop tap which passes directly into the bag of a Clover's inhaler. By this means as much ethyl chloride as is required is sprayed into the bag, and then the tap turned off; the administration may thus be continued indefinitely.

Mr. G. P. NEWBOLT showed a male patient, *æt.* 38, from whom he had removed a large colloid carcinoma of the cæcum, six months previously. The growth had caused no obstruction; it was removed through a transverse abdominal incision, the resulting scar being an excellent one. He also related a case of intestinal obstruction occurring in a female, *æt.* 53, for which he had performed left inguinal colotomy. There was a marked sigmoid curve, and the fæces passed through the lower opening of the colotomy wound. Three months later the carcinomatous growth causing the obstruction, and the artificial anus, were simultaneously excised. The patient made an excellent recovery.

MR. K. W. MONSARRAT read an account of a case of FRACTURE OF THE FEMUR IN A HÆMOPHILIAC.

The patient was a boy, *æt.* 8. At the seat of fracture there was an enormous local effusion which progressively increased up to the fourteenth day, and was accompanied by a steady rise of temperature. His personal history indicated hæmophilia, and he showed signs of the disease elsewhere during his stay in hospital. Union of the fracture took place early; by the end of the fourth week it was already firm. The local effusion simulated an inflammatory condition, and before the personal history was inquired into, it was looked upon as probably of this nature.

Mr. DOUGLAS CRAWFORD referred to a case of hæmophilia with effusion into the knee-joint, in which, on account of the pain and temperature, simulated acute arthritis. He opened the joint, and a satisfactory recovery followed.

Dr. HUGH R. JONES read a paper on the distribution of

PHTHISIS AND CANCER IN ENGLAND AND WALES. Having pointed out the difference in the age and sex incidence of the two diseases, he drew attention to certain similarities in their history and distribution. It was proved that cancerous persons had a family history of phthisis greater than obtains in the general population, and that a high percentage of phthisical persons had a cancerous family history. The two

diseases are more prevalent near the sea-line. Cancer areas either overlap, or are contiguous to, phthisical areas. In central England, both cancer and phthisis are below the average. The death-rate from phthisis reaches its zenith at the 35-45 age period, the period at which the cancer death-rate begins to increase. He pointed out the frequency with which arrested phthisis and obsolete tubercle were found in cancerous persons. He believed that the recorded increase in cancer was in part real, and not altogether explained by improved diagnosis, nor by the increased population living at higher age periods, owing to the fall in the general death-rate, which would not affect the cancer death-rate, but probably due to the fall in the phthisis death-rate, resulting in members of phthisical families surviving to the cancer age, such persons being more prone to cancer than the general population.

Dr. WILLIAM CARTER thought that on the question of cancer and phthisis one might well consider, side by side with statistics, certain great changes in the national habits. Ever since the Registrar-General's office had been founded, some seventy years ago, a steady advance in the mortality from cancer had been recorded. Within that period bleeding, which at first was universal, had been totally discarded; the use of mercurial compounds, the greatest of antiseptics, like bleeding once universal, had been largely abandoned. The consumption of meat per head of the population had probably increased many times over, and the people who had lived simple natural outdoor lives had become aggregated in dense masses in towns. It was quite open to consideration whether all these great facts might not be related to each other.

Dr. R. J. M. BUCHANAN recognised the importance of the peculiar fact that in many cases of cancer obsolete tubercle was found *post-mortem*, and also the close relationship in family history between tuberculosis and cancer; but he did not consider that the increased death-rate from cancer proved increase of incidence as real, or that it in any way depended upon the lowered death-rate from phthisis. The prophylaxis exercised against tuberculous infection by lowering both the incidence and death-rate from phthisis had resulted in more persons now living until they reached that period of life in which cancer is recognised as most likely to occur.

Mr. K. W. MONSARRAT said he did not consider that any particular relationship had been established as existing between cancer and phthisis.

Dr. J. HILL ABRAM thought the chart of Dr. Jones, illustrating the marked difference between the apparent and the corrected death-rate from cancer, was very important, and demonstrated the great care necessary in dealing with figures.

#### LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 4TH, 1904.

A MOST interesting specimen of

ACTINOMYCOSIS IN THE TONSIL of a female child, together with bacteriological sections, was shown by Mr. ARTHUR CHEATLE and Dr. EMMERY. It was agreed that this was probably the second case only which had ever been recorded of actinomycosis in that region.

Several specimens of malignant disease in the upper air passages of the dog and cat were shown by Professor HOBDAY and Mr. DE SANTI, and an interesting case of probably extrinsic malignant disease of the larynx in a man, *æt.* 64, by Dr. FURNISS POTTER.

The case was unusual in the fact that it had lasted some eighteen months without any glandular infection. It was looked upon as a particularly suitable case for laryngectomy.

An interesting specimen of a foreign body—a collar-stud—was brought forward by Dr. PATERSON, the foreign body having been removed by direct laryngoscopy, Killian's method, from a child, *æt.* 12 months.

Mr. WAGGETT brought forward a diagnostic speci-

men from an oesophageal stricture removed by Killian's method. He pointed out that oesophagoscopy in England seemed not to be as well known, as a method of diagnosing strictures of the oesophagus, as it should be.

Mr. DE SANTI showed a case of curious erythema of the soft palate and tonsillar region in a girl. The question was as to the nature of the trouble. One or two members looked upon the case, though unique, as probably of the nature of angioma.

Dr. KELSON showed a case of laryngeal growth in a boy, *æt.* 6, the interest of which was that the growth had been removed in the sitting-up posture by endo-laryngeal forceps and deep anaesthesia.

Mr. H. B. ROBINSON showed a case of pharyngeal obstruction from a diaphragm which stretched between the back of the tongue and the posterior wall of the pharynx.

Dr. LAW showed a case of stenosis of the trachea, ozænic in nature, and Dr. DUNDAS GRANT a microscopic slide of an extrinsic laryngeal growth, the diagnosis resting between sarcoma and fibroma.

#### CHILDHOOD SOCIETY.

MEETING HELD NOVEMBER 10TH, 1904.

SIR JAMES CRICHTON BROWNE in the Chair.

Dr. THEO. B. HYSLOP began by saying that alienists had before them a problem asserting itself with overwhelming force, the percentage of insanity having quadrupled itself in fifty years, these figures not including imbeciles, hysterics, drunkards, neurasthenics, or the feeble-minded, but simply those under control. With regard to physical training in youth, it had to be borne in mind that school games involved a wide range of mental activity, and the boy fresh in from a strenuous game was not fitted to use his brain to a similar effort. Athleticism and games must be complementary. A severe strain in either course when young was felt all through life.

All were agreed as to education, but to force any mental effort on stunted, underfed children was both inhuman and impolitic. Half the children in Board Schools were unfit for lessons, and it would be cheaper to feed them than to pay for them afterwards as pauper lunatics.

Acute mania had not increased so much as that weak-mindedness which might be regarded as a product of the last few decades.

The mental condition at the present day was one of psychorrhœa gravis. There was diffuse consciousness, ill assortment of ideas, and a lack of seriality of thought easily passing into a state of insanity.

That loss of memory so frequently noted in the papers really marked a form of epilepsy. There was a want of economy in brain power. It did not appear that education, so-called, had done much when efforts had to be made in the way of workhouses, almshouses and asylums to keep pace with increasing insanity.

In concluding, Dr. Hyslop spoke of our unphysiological daily habits. The turning night into day and having to sleep when the brain should be at its brightest. Theatres and concert halls should be closed at ten. In fact, we were two hours too late in everything, and the results, although apparent in us, were manifested chiefly in our progeny.

SIR JAMES CRICHTON BROWNE, in reply, said it was impossible to ignore the weakness of a social system which led to increase in wastrels, criminals, lunatics and juvenile delinquents, and the remedy lay, as Dr. Hyslop had pointed out, in proper care of the young when the association fibres of brain were forming irresistible habits of mind and body. Clever people had more of these fibres than others, but in all brains they were forming pathways made indelible by use. Our annual lunacy returns ought to silence the genial optimist who drags the public by pretending these are unreliable. Brudenell Carter says the attempt to explain away the larger number of lunatics is puerile. Physical deterioration must involve the

brain, and inquiry into its cause and cure was quite as momentous as that into cancer or tuberculosis.

He (Sir J. C. Browne) also agreed with Dr. Hyslop that from a purely scientific point of view some kind of religious instruction was necessary.

#### ASSOCIATION OF PORT SANITARY AUTHORITIES.

THE annual meeting of this association was held at the Westminster Palace Hotel. Alderman C. H. Giles, chairman of the Liverpool Port Sanitary Authority, was elected President, in succession to Dr. Fraser (Hull), and took the Chair. In thanking the members for the honour conferred upon him, he said the Association increased every year in importance, and it was doing good work for the community at large. Alderman Hindmarsh was elected Vice-president, and other officers were appointed. Mr. R. Sheriton Holmes, the hon. solicitor, read some notes on "The Association of Port Sanitary Authorities' Expenses Bill," which provides for the expenses of representatives attending meetings and the payment of a subscription to the funds of the Association. He suggested that the sixty port sanitary authorities in England should be asked to memorialise the Government in favour of taking up the Bill, and a resolution to that effect was adopted. In a paper on "The Recent Case of Plague in the River Tyne," Dr. W. E. Harker said it was probable that the patient developed the disease by direct inoculation from rat infection, although no definite point of entrance or insect bite could be demonstrated on the skin. The case afforded further proof of the great danger of plague-infected vermin on board ship. Dr. E. W. Hope (Liverpool) and other members said the case illustrated the importance of the systematic destruction of rats in all vessels coming from plague-infected ports. A discussion on "Amendments in the By-laws relating to Infectious Disease" was opened by Dr. Hope, who said the present penalty of 40s. for breaches of the regulations by masters of vessels was wholly inadequate. He suggested that it should be raised to £50 or £100. The question of the desirability of the taking of samples of food for analysis by port sanitary authorities under the Food and Drugs Acts was brought forward by Dr. J. Wright Mason (Hull), and after a brief discussion the matter was referred to the council. The meeting also referred to the council for consideration the subject-matter of a resolution by Dr. A. M. N. Pringle, the Medical Officer of Health of the Manchester port sanitary authority—which that gentleman afterwards withdrew—in favour of the control of the sanitary arrangements of mercantile vessels, both during and after construction, being vested in port sanitary authorities.

#### CANCER OF THE BREAST.

THERE exist two kinds of cancer, says Professor Mauclair: encephaloid and scirrhus. Two other affections in the cancer group must be detached, sarcomata and cysts. Encephaloid cancer is characterised by an insidious and painless *début*, wherein lies a grave danger, as women do not take much notice of it, and in the meantime the tumour develops both in depth and in surface. The adhesions it contracts with the skin produce the classical orange-peel appearance.

Soon the nipple retracts, ganglions appear in the axilla, and the skin ulcerates. It is necessary to diagnose at the outset such a grave affection, as the average duration is from eighteen months to two years.

Scirrhus is found generally in aged persons, while the encephaloid form attacks women between forty and forty-five years of age. The former constitutes a tumour of small dimensions, hard, producing atrophy of the gland. The duration of the malady is from ten to fifteen years. Either of these forms should be distinguished from numerous other affections of the

gland, firstly, *cutaneous epithelioma*, which is developed in the skin; the deep tissues are not affected, and the malady is easily recognised. Then comes chancre of the nipple, observed generally in young women; the tumour is round and the edges indurated. Syphilitic gummata can be found in the mammary gland, but the ulcerous and phagedenic character of the affection is sufficient to remove any doubts.

Other affections more rare might simulate cancer, such as submammary tumours (cold costal abscess, exostosis, lipoma), which push the gland forward. The same may be said of certain tumours which have been confounded with cancer. Cold abscess of the breast, mammary tuberculosis characterised by tuberculous granulations disseminated throughout the gland. *Cystic disease* of the breast, described in France by Reclus, is a bilateral tumour, symmetrical from the outset. The ganglions are not affected, and the affection remains stationary.

*Chronic mammitis* is one of the affections most frequently confounded with cancer. This malady appears, like the encephaloid tumour, at the close of uterine life, and is to be found in patients who had heretofore abscess of the breast. In palpating the gland from before backwards, small, irregular masses are felt, painful to pressure. Encephaloid cancer is not painful to pressure, is not bilateral, as is frequently the case with the chronic affection. The diagnosis is often difficult, and frequently only the treatment will clear up the nature of the affection. Elevation and compression by cotton wool of the breast produces improvement and retrogression of the masses in chronic mammitis, while no such favourable modification is ever observed in cancer.

*Adenoma* of the breast is easy to recognise. It is a little tumour which appears in young women; it is round, capsulated, and painful. Sarcoma is recognised at first glance. It is an enormous mass run over with a network of subcutaneous veins, and presenting cystic degeneration in places. The development is rapid, and no ganglions are found in the axilla. The prognosis is subordinate to the variety. Scirrhus can last twenty years, but it can also degenerate, hence the danger. The encephaloid form kills in two years, but there are many exceptions to this rule.

The treatment is naturally total ablation in both cases as early as possible, and by this means life is prolonged two or four years, or even more.

Another method of operating for cancer is ablation of the ovaries. According to M. Regnès, of Marseilles this operation is capable of producing retrogression of the tumours.

BERLIN, November 12th, 1904.

At the Naturforscherversammlung, Hr. Kövesi gave a communication on

#### DROPSY IN RENAL DISEASE,

based on observations made in the First Medical Klinik, Budapest. As regards its origin, there was no unanimity of opinion. After investigation of the tissue changes and cyroscopic examination of patients in Kóran's Klinik, it was believed to lie in the deficient excretion of water. For the purpose of the functional testing of the kidneys he recommended the dilution investigation (*Berl. kl. Wochenschr.*, Bd. 15, 1900), which rendered it possible to test the power of the kidneys to eliminate water. The organism with renal disease had no power of compensating the deficiency in the excretory power in any extra-renal way, therefore paralysis of the water-secreting apparatus caused retention, thus storing up fluid in the body. The retained water associated itself with the blood. It must therefore cause hydræmia. It might be assumed that the wall of the capillary vessel offered a certain resistance to heightened filtration pressure, which must be overcome before dropsy can arise, but it was not the only

factor. When the tissue was damaged in its elasticity in consequence of the burdensome high pressure, its power of forcing the tissue juices into the lymph tracts was also injured. In cases of mechanical blocking of urine special conditions prevailed, in consequence of which the cases ran a tolerably monotonous course without œdema and without any typical uræmia, but generally with symptoms of increasing bodily and mental decay. This subject had, however, not been much inquired into, and for this reason no decisive importance had been given to it. No cases of œdematous nephritis were observed in which any essential limitation of the dilution fluid could not be determined. Occasionally, in cases of nephritis, œdema of inflammatory origin independent of the typical insufficiency of elimination might be met with. The typical nephritic œdemata, however, were independent of the kidney condition. Considered from the clinical side, the secretion of water and the capacity of dilution of the kidneys outside the condition of these organs themselves depended on functional power of the heart. The speaker considered the genesis of dropsy, both in renal and cardiac diseases, to be the same. He attributed dropsy from heart affection to renal stasis due to hydræmic plethora and favoured by diminution in the rate of flow of the blood.

Hr. Kretz, Vienna, spoke on

#### CIRRHOSIS OF THE LIVER,

and said it was not dependent on interstitial hepatitis, but the parenchyma itself had become changed by regenerative healing of multiple attacks of degeneration. The appearance of elastic fibres in the connective tissue of the cirrhotic liver was essentially dependent on the fresh melting together of parts of parenchyma with free arterial supply, and already built around or walled in. The first anatomical change did not lie in the connective tissue, but in the patch-like degeneration of the parenchyma and in the subsequent wedging in of regenerated tissue in the region of the section of parenchyma with a better arterial supply.

Cirrhosis of the liver was not a morbid entity; the liver change was rather an anatomical sequence of repeated degeneration of liver cells with parenchymatous new growths thrust in between. Etiologically, the disease might be set up by any of the pathogenic influences that caused degeneration of the parenchyma; by abnormal tissue changes, by poisons, by bacterial injuries, and the injurious substance might reach the liver cells either by way of the blood tracts or by the bile capillaries.

Hr. Naunyn, Strassburg, had come to the following conclusions. There were distinctly various forms of the disease. It was well to distinguish (a) commencing cirrhosis; (b) the common ascitic cirrhosis (the atrophic form); (c) biliary (hypertrophic) cirrhosis; (d) the hypersplenic form of Banti's disease. The difference of these forms did not rest on any original difference in the morbid process, but on the complicating cirrhotic cholangitis, which was present in varying degree and in the most varied manner. This cirrhotic cholangitis was an enterogenous ascending cholangitis; it was not the cause of the cirrhosis but a complication which affects the organ already cirrhotic. The separation of enterogenous and splenogenous forms had no basis of fact, but, on the other hand, the hæmatogenous origin was probable. There might be hæmolytic processes in play, and if a cirrhotic cholangitis was present it would be a descending cholangitis of hæmolytic origin.

Hitherto only the alimentary leucosuria was recognised as a symptom of disturbed hepatic function, but even of this it has not been proved that it cannot be caused by the direct entrance of sugar into the blood. Diagnostically, therefore, characteristic anatomical changes were requisite. Lichtenstein's præcirrhotic splenic tumour was not proof of the "up-to-the-present-not-diseased-condition." Banti's disease was not specific. The cases resembling biliary colic were caused by infectious inflammation of the bile passages. Etiologically, alcohol was almost the only substance to be accused. The changes found by Bleichroeder were only consequences of the liver disease.

Aufrecht said there was only an apparent increase in the connective tissue, and this was caused by shrinking of the acini. Chiari, Prague, laid stress on the enormous new growth of the liver parenchyma, and also the interstitial secondary processes—frequently necrosis of the liver. V. Hansemann, Berlin, considered the alcoholic origin of the disease still undecided.

#### QUANTITATIVE ANALYSIS OF BLOOD OXIDATION.

At the meeting of the "Naturforscher," Jolles presented a report on the analysis of blood and its catalytic power for oxidising. In this investigation he was assisted by Dr. Oppenheim who provided him with an extensive supply of clinical material. The principle of this analysis is founded on the comparative changes that take place in hydrogen peroxide ( $H_2O_2$ ).

His method of procedure is to take 0.05 cubic centimetre of blood in a capillary tube and place it in a measured 50 centimetres flask with 30 cubic centimetres of a physiological salt solution. The tube is finally rinsed out with another 20 cubic centimetres of the salt solution, making up the flask to the 50 centimetre mark. Ten centimetres of this blood solution is now mixed with 30 cubic centimetres of the peroxide of hydrogen, and the mixture allowed to stand for two hours at summer temperature. The next process is to acidify with  $H_2SO_4$ . Add a few drops of an iodide of potassium solution, and then titrate with the thio sulphate solution. The difference obtained between the 10 cubic centimetres of the blood solution, or 0.01 of the blood and a peroxide of hydrogen solution ( $H_2O_2$ ), will give the catalytic power of the blood. This catalytic number will be found to range between 18 and 30 in normal blood, but more commonly between 20 and 26. Male and female blood do not differ, neither does the arterial differ from the venous.

In special diseases, however, like tuberculosis, nephritis, and carcinoma, the value falls to between 1 and 10. This may be of considerable clinical value in cases of doubt, and where confirmation is required.

#### TESLA'S CURRENT IN TUBERCLE OF THE LUNG.

Stenbeck drew the attention of the meeting to Tesla's current in cases of pulmonary tuberculosis. Doumer, Oudin, and others had obtained good results according to their descriptions, but he was now convinced from long experience that the current must be very strong before any beneficial effects can be realised.

The so-called "effluvien" must be 15 or 30 centimetres, or about 6 to 12 inches, to be of any use, while the "inductorium" should be 50 to 60 centimetres for a spark. Without change of residence or food these cases when so treated take on body-weight and subjectively seem greatly improved. Notwithstanding this favourable result, it would be premature to form any conclusive judgment on the point.

#### INTERNAL EFFECTS OF FORMALDEHYDE.

Jakobson gave a history of the drug and its physiological effects on the human organism. The best way of administering the remedy was with sugar or milk, which relieved the irritation. In his own experiment 31 per cent. of the drug administered passed off by the kidneys, the rest being decomposed into formic acid, carbonic acid, and the remainder entering into combination with albumen.

Rosenberg said that he had used formaldehyde in many hundreds of cases without a single bad result, although his treatment ranged over angina, scarlet fever, diphtheria, erysipelas, and cystitis. The dose prescribed never exceeded 1 to 2 decigrammes per day in the form of a 1 per cent. solution, with milk of sugar, or in tablets.

Weintraud remarked that formaldehyde forms an insoluble combination with urea and uric acid, which

may explain the poor results obtained from citarin where it is in combination with an alkali.

Stern said that he had used large doses of urotropin, and never could find formaldehyde in the blood serum.

Müller observed that although it was true the elimination of uric acid was checked, the action on calculi in the bladder was powerful. Gout was not benefited by its use.

## The Operating Theatres.

### NORTH-WEST LONDON HOSPITAL.

**OPERATION FOR SYPHILITIC STENOSIS OF THE LARYNX.**—Mr. MAYO COLLIER operated on a case of stenosis of the larynx, that first came under his care some ten years ago. He said this was a unique case of its kind. The patient, a female, æt. 28, had presented herself at his out-patient's department ten years ago complaining of extreme difficulty of breathing. The history of the case was the following: She had been married four years. Six months afterwards she had been affected with a secondary eruption and a sore throat, and subsequently gave birth to a child that died in early infancy. Since then she complained continuously of laryngeal troubles, associated with cough and expectoration of blood-stained sputa. On examination it was found that the whole of the upper opening of the larynx was occluded by a cicatricial membrane leaving but a small opening, the calibre of a lead pencil, near the root of the epiglottis; the epiglottis itself had disappeared and was now represented by a stump the size of a small pea. Mr. Collier ascertained the woman had been affected with syphilis in early matrimony, the husband having suffered from well-marked syphilis. The then condition had been brought about by an attack of acute laryngeal catarrh, rendering the extremely limited opening for respiration still further curtailed. The case was immediately admitted into the hospital and tracheotomy performed. Mr. Collier said that at the end of fourteen days the patient left the hospital wearing a tracheotomy tube, which afforded satisfactory space for respiration. On two subsequent occasions the patient was re-admitted into the hospital, and an attempt was made to enlarge the stenosed upper orifice of the larynx. Under cocaine on both occasions an incision was made to the right and left of the stenosed orifice; the cicatricial tissue was so firm and rigid, however, that no increase of space was obtained. The patient now presented herself, having worn a tracheotomy tube for nine years, and having in the interval acted in the capacity of cook in various establishments, complaining of difficulty of breathing, difficulty of replacing the tracheotomy tube, and serious hæmorrhage at each attempt. Mr. Collier dilated on the importance of this case, and the fact that the patient had been quite comfortable for some nine years without any attacks of laryngeal catarrh or bronchitis, and had been continuously in domestic service during the whole of this period. With a good light and with the assistance of a pair of dilators he demonstrated to those around a mass of granulations not only extending into the trachea but surrounding the outer opening of the tracheotomy wound. He demonstrated with the laryngeal mirror the upper opening of the larynx, which apparently was unaltered since his first examination some nine years ago. It was now, as then, of the size of a cross section of an ordinary lead pencil. He said that this case was most encouraging so far as the operation of tracheotomy was concerned. The

patient had been able to change the tracheotomy tube daily, and had enjoyed a period of comparative comfort for some nine years. It was, he thought, astonishing that the granulations round the tube should not have given trouble before this. After placing the patient in a semi-recumbent position, with the aid of a good light he introduced a 20 per cent. solution of cocaine and adrenalin into the tracheal wound; with the aid of a pair of tracheal dilators he demonstrated to those around a fringe of polypoid granulations invading the tracheal canal; externally a similar mass of granulations on a level with the skin was equally apparent. He next introduced a curved Jarvis' snare, and removed the granulations one by one in each direction. The external granulations were removed with a pair of scissors and forceps, and a large-sized silver tracheotomy tube introduced, and the patient returned to bed. Mr. Collier remarked that in these cases of syphilitic stenosis of the larynx the patient in the course of time did not improve, for, as a rule, the stenosed orifice became more occluded and there was a great tendency to cicatricial contraction of any opening made into the trachea or elsewhere. He intended to retain this patient in the hospital till she was able to wear a silver tracheotomy tube of the largest size before discharging her; after which it was possible she might go another nine years without further surgical assistance.

**POLYPUS OF THE RECTUM.**—The same surgeon operated on a girl, æt. 14, who had suffered for the last four or five years from rectal irritation associated with a discharge of bloody mucus. The history of the case was that the child had complained of some irritation about the rectum and bladder for several years, there had been frequency of micturition, with pain and tenesmus after stools for a considerable period. Examination showed a polypus about the size of a filbert nut attached to a long pedicle, which was hanging from the right wall of the rectum. Mr. Collier pointed out that in this case the sphincter ani was apparently quite inert, the finger could be introduced with the greatest ease, and the polypus withdrawn. He withdrew the polypus with a pair of catch forceps, applied a ligature at the base of the pedicle and removed it with scissors. He remarked that this was an unusually typical and simple case, and required no after-treatment or dressing. He said the condition of the sphincter ani was apparently due to the presence of the polypus within its lumen.

### A New Scholarship for Pharmacy Students.

MESSRS. FAIRCHILD BROS. AND FOSTER, of New York, in order to mark their "appreciation of the friendly relations which have existed for many years between the firm and the pharmacists of this country," have inaugurated a scholarship of the annual value of £50, with consolation prizes of £5 each, to be awarded to the *proxime accessit* in each country—England, Ireland, Scotland and Wales—the examination centres being London, Manchester, Dublin, Edinburgh, and Cardiff. The first examinations will be held simultaneously in July next year. Candidates must be between twenty and twenty-two years of age, and duly registered and affiliated to either the Pharmaceutical Society of Great Britain or the Pharmaceutical Society of Ireland. The subjects of the examination are simply those with which the student would be expected to have ample acquaintance in any reasonably equipped pharmacy. Further particulars may be obtained by application to the secretary of the Committee of Trustees, A. E. Holden, Bath House, 59 Holborn Viaduct, London, E.C.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 16, 1904.

**THE ABUSE OF HOSPITALS.**

THE complaint against hospital abuse is as old as the hills, and the demand for its reform dates from a period prior to the birth of medical journalism. In spite of the lapse of years, however, no great practical step has hitherto been taken towards putting a stop to the evil in question. The *crux* of the whole matter lies in the fact that the medical charities are controlled by philanthropists who are not in touch with the main body of the medical profession, while the honorary medical staffs of those institutions apparently know little, and care less, about the practice which their gratuitous service abstracts from outside practitioners. If the hospital surgeons and physicians generally took up a firm and sympathetic position upon the whole subject, we believe that within a week the question of hospital abuse could be reduced to a satisfactory basis of settlement throughout the United Kingdom. That proposition we commend to the notice of Mr. F. Harris White, the energetic secretary of the East London Medical Society. As most of our readers will doubtless remember, while others have been content to sit still and grumble, the Society in question has brought matters to a head by a polite but insistent criticism of the way things are conducted at the London Hospital. That particular charity is no better and no worse than other institutions of the kind, but it provides for an enormous population, and happens to fall within the field of operation of the Society of which Mr. Harris White is secretary. Last May a deputation of that body waited on the Board of Management of the London Hospital to ask for reform of certain abuses in the administration of relief. The first great step gained was an admission of the existence of the abuses complained of, although they had previously been repeatedly denied in the public press by prominent members of the London

Hospital Committee. The Medical Society's complaint fell under the two heads of the system of part payment by patients and of want of scrutiny as to means of applicants for relief. The hospital authorities admitted the existence of abuses, as already stated, and, further, that in the casualty room scrutiny was non-existent. The precautions now adopted seem good, so far as they go, but, while not abandoning the part payment system, they put up notices stating that patients' payments are for dressings and other value received, and not for medical advice. Other steps include the obviously essential one of registering the address of patients, which the authorities place at the disposal of local practitioners who may wish to inspect them. It seems clear, however, that no hospital should be permitted to shirk its responsibilities by thus foisting a system of espionage upon the members of an honourable profession. It is the hospital that sins in giving charitable aid to the well-to-do and not the outside general practitioner. A similar objection applies to the offensive and grotesque suggestion of the hospital that outside medical men should visit the out-patient departments in order to detect unsuitable patients. This proposal is in itself sufficient amply to illustrate and to emphasise the contemptuous attitude of hospital philanthropists in countering the home-thrusts of an injured profession. Fortunately, the East London Medical Society is able to press a skilful as well as a strong attack where generations of unorganised protest have failed to make the faintest impression. The hospital next proposes to send patients who can pay small fees to the Metropolitan Provident Dispensary over the road. This cynical evasion of a just demand certainly does not add to the respect to which the London Hospital management should be entitled, and we trust they will abandon this unworthy suggestion. They propose to call in the aid of the Jewish Guardians and of the Charity Organisation Society to exclude unsuitable patients. The latter body is certainly likely to drive away patients, but we were under the impression their help had been secured years ago by the London Hospital. The most reassuring proposal by the committee is that the home of every patient should be visited the day after admission, and if found to be unsuitable he or she is to be discharged and a donation demanded on behalf of the hospital. This sounds well if it could be made practicable in so large an institution. The upshot of these negotiations will, we trust, be an amicable working agreement between the London Hospital and the medical profession of East London. Should that happy result not follow, it is possible for the members of the Medical Society in question to bring pressure of a most convincing and effectual nature on the consulting surgeons and physicians of the honorary staff of the hospital, as we have already pointed out, in whose hands the key of the situation most undoubtedly lies. The honorary staff is to a great extent dependent on the goodwill and friendship

of the outside general practitioner, and the work of the hospital depends on the gratuitous services of the medical and surgical staff.

#### MUSIC AND MEDICINE.

THE field of therapeutics is rapidly widening, and the resources of every art are being continually tapped to add to the weapons of the physician. "Sweetness and light" have to a great extent supplanted nastiness and draughts in the treatment of disease, and the patient of to-day may console himself amidst the trials of modern life with the reflection that his lot in the hour of sickness was not cast in the "good old times." To bring music into requisition as a means of dealing with the sick has long been hankered after by one person and another, but beyond the now orthodox asylum band, little progress has been made in the application of sweet sounds to disturbed bodies and brains. The subject is, however, being taken seriously in hand by a certain body named the St. Cecilia Guild, who have mapped out an ambitious programme for themselves. They propose first to study by investigation the extent of the influence of music on the heart, blood pressures and respiration; at least, that is the initial item mapped out in their prospectus. We do not wish to damp their enthusiasm, and we shall be very glad if they are able to add anything useful to medical knowledge as the result of these investigations, but we rather fear that the line of research that they are proposing to follow will prove a somewhat barren one. True, Dogiel has announced in his work, "Experiments on Men and Animals," that music is capable of raising or depressing the blood pressure under varying circumstances—such as the disposition and susceptibility of the subject, and the nature of the music performed—and he has found also that the pulse- and respiration-rates were affected under the same conditions—a result attributed to the influence of stimulations of the auditory nerve acting reflexly on the vaso-motor nerves through the sympathetic system. Without gainsaying the accuracy of these statements, it has yet to be shown that the influence of music is sufficiently potent and durable to produce effects on sick people that are of practical utility. Music can undoubtedly make a strong appeal to the emotions of sympathetically-attuned persons, but its influence soon passes off, and is not in bulk much greater than that exerted by the reading of an exciting or soothing story-book. The St. Cecilia Guild, however, seem to have made up their minds on the therapeutical utility of music, for their second object is to organise a body of special musicians, vocal and instrumental, who will be available at any time of the day or night to attend on patients at the doctor's order, and perform music of the character he prescribes. No doubt can exist as to the enthusiasm of a player who is ready at a moment's notice to turn out of bed to perform Beethoven's Moonlight Sonata or to recount the vagaries of Bill Bailey according to the

whim of the invalid or the fancy of the doctor, but we are inclined to think that in the present state of medical opinion the slumbers of the members of the Guild and that of the patients' neighbours are not likely to be seriously encroached upon—in this country at least. In order, however, to obviate any remonstrances from disturbed and unappreciative persons, an alternative course has been devised, namely, to establish some central building for the continuous performance of music which can be enjoyed by telephone or electrophone by the sufferer in his bedroom. This plan is certainly open to less objection, but there is something rather pathetic in the idea of these willing ministers to the sick discoursing music, with an infinity of expression and care, without knowing whether or not they are being listened to, or if their performance is one that is suited to the patient's particular case. For, if music is to be beneficial in its effects, the first consideration is that it should be appropriate to the state it is desired to induce. "Bill Bailey" might act as a charming lullaby to a Cockney child, but there are others who would find it positively irritating. If that were the item selected for continuous performance through the telephone on any particular night, some sufferers, at least, would find sleep further off than ever after listening to its haunting melody. Dr. Kennedy, of Brooklyn, believes that the field of action of music reaches into all departments of medicine, including surgery and dentistry, and would have the occupant of the dental chair soothed and sustained by the quieting influence of music. In a paper read before the Medical Society of King's (N.Y.), he warmly advocated the extended use of music in the treatment of the sick, and gave demonstrations of the methods of administration and of the effect music of a certain character might be expected to produce. Perhaps the most practical suggestion that has been put forward as yet is that music should be used as an adjunct to anæsthetics, calming and diverting the patient's mind till consciousness is lost. It is said that a number of test cases have been treated by this method in Germany, and that there was absence of distress and resistance on the part of the patient, and also absence or reduction of nausea and sickness following the operation. This is good news, of course, but most medical men will hope that the fact may not become too widely known. The paraphernalia of the anæsthetist are sufficiently cumbersome already without his having to add a gramophone or musical-box to his equipment. The real fact would seem to be that the use of music as a therapeutic agent is but a small one, and though it may have some use as an ancillary, it is not likely to have much as principal agent in the treatment of patients.

#### Notes on Current Topics.

##### Paिताosis.

DOMESTIC animals are not always unadulterated blessings, and unless well watched and cared for

may become sources of infection to the household in which they live. Cats may convey diphtheria; dogs give rise to worms, whilst birds have been suspected of tuberculous leanings. Vickery (a) quotes several outbreaks in households of a condition remarkably like typhoid in which the infection probably originated from parrots. The disease, as a rule, sets in sharply with febrile symptoms, but the onset may be insidious. The fever is continuous and ends by lysis; constipation is usual, but there may be diarrhoea; enlarged spleen is invariable and a roseolar eruption may be associated with it; whilst foci of pneumonia commonly are found in the lungs. Vickery himself has met with a group of three cases of such an illness, which followed the arrival of a parrot in the house. The bird suffered from a bloody diarrhoea, and died, passing the time of its illness in one of the sitting rooms. There were four members in the household, and of these the only one not affected had little to do with the bird. The first patient was the servant who looked after it, and she sickened eighteen days after the parrot's arrival; the other two victims followed in a few days. From the descriptions given of psittacosis, Vickery is of opinion that his cases should be placed under that heading. The bacteriological examination results were indefinite, but none of the ordinary recognisable organisms were found. As the bacteriology of psittacosis is doubtful, the findings were so far in its favour. It is always well to inquire after the health of domestic pets when any member of a household is taken ill from obscure causes, and even the parrot in his cage should not escape the general suspicion.

#### Clever Malingering.

THE man Cecil Brown Smith, sentenced to three months' penal servitude last week at the Guildhall for collecting alms under false pretences, is quite a notable figure in the annals of crime. His career of late years presented one of those extraordinary patchworks that we are accustomed to associate with a certain class of criminal—obtaining money under false pretences in the day, leading a respectable domestic life at home in the evening, and varying these proceedings with playing billiards, visiting places of entertainment, and preaching at Salvation Army meetings. But the real interest of the case from the medical point of view was his imitation of paralysis. Some time ago Smith had an accident and declares that, as the result of this, he suffered from paralysis of the right side. That he did so is not very clear, but he was certainly an inmate of St. Thomas's and afterwards of the National Hospital for Paralysis. Whatever was wrong with him at the time he recovered sufficiently to enjoy himself after his manner soon after coming out, and whilst in hospital he had learned a profitable way of earning a living. This was by feigning right hemiplegia—as he had seen it in the wards, and posing as a paralysed beggar in the City. His

imitation is said by those who saw him to have been wonderful, the side of the face being drawn down, the right arm and hand stiff and rigid, and the right lower limb dragged wearily along. So good was his impersonation of the part that he was freely made the recipient of alms by generous passers-by, and he earned upwards of six pounds a week by the deception. Even when examined by the surgeon at the police-station he was not non-plussed, as he had noticed in hospital the tests applied to patients for purposes of diagnosis, and how to counterfeit the responses of those who were really diseased. It was only when he found the game was up by the appearance of witnesses who had seen him in full possession of his powers that he shook off his paralysis and appeared in the dock in his natural active condition. His case was certainly one of the most successful and—if we may say so—artistic in the history of malingering.

#### Municipalities and Bacteriology.

As our readers are aware, many of the more progressive municipalities, at home as well as abroad, have seen fit to undertake the bacteriologic examination of suspected clinical material, thereby giving aid to the practitioner in his labours on behalf of the public health. Liverpool, Manchester, and many other cities have appointed bacteriologists whose duty it is to examine material sent to them by any medical man in the town. For instance, in Manchester, every practitioner is supplied by the Medical Officer of Health with apparatus for the transmission of sputum, diphtheritic membrane, blood for the agglutination test, and so on, and he is encouraged to ask the help of a skilled bacteriologist retained by the city in such questions of diagnosis. The question of the appointment of a bacteriologist to the City of Dublin has been under discussion now for some time, the Public Health Committee having recommended such an appointment. Dublin can certainly not afford to overlook any precaution which might improve the public health, as it still maintains its pre-eminence as almost the most unhealthy city in Europe. It is, moreover, decimated by tuberculosis, and the early diagnosis of phthisis would undoubtedly tend toward the public good. Nevertheless, the Dublin Corporation has decided to postpone the question for two years. This decision is all the more culpable as the expense would be inconsiderable. There are several laboratories in Dublin, public and private, with any one of which it would be easy to arrange the examination of clinical material at moderate rates, and where the payment could be arranged, either at a fixed sum per annum or in proportion to the work done.

#### Recent Appointments at the Royal University.

THE Council of the Royal University Graduates' Association, an association which appears to be almost entirely limited to Belfast graduates, have adopted a strongly worded resolution in protest against the manner in which the recent vacancies

(a) *Med. News*, October 22nd, 1904.

on the Senate of the University have been filled. The resolution is as follows:—

"We, the Council of the Royal University Graduates' Association, desire to express our deep sense of indignation at the grave injustice inflicted upon the North of Ireland by the Irish Government in their recent appointments to the three Crown vacancies on the Senate of the University. Notwithstanding the fact that the Belfast Medical School contributes more than half of all the candidates in the Faculty of Medicine, the Irish Government have appointed as successor to the late Dr. W. A. M'Keown, Sir W. Thomson, a Dublin surgeon, who does not represent any school connected with the University, and whose appointment leaves the Belfast Medical School without a single life representative on the Senate or on the Medical Committee. We regard the selection of Sir W. Thomson as a studied slight to graduates of the University, in view of the fact that during the time he represented the Convocation on the Senate his policy was objectionable to the graduates, and recently when he sought reelection he was defeated by a large majority. The Council cannot but consider that the action of the Government is a retrograde departure from principles on which the University was established, and a deliberate attempt to neutralise the very meagre influence originally bestowed upon the Convocation by the Crown. The Council, therefore, are reluctantly forced to the conclusion that the Government, by their depriving the large and important community whose views the late Dr. M'Keown so ably advocated of a representative on the Senate, are deliberately endeavouring to promote a spirit of discontent with the present University system, in order the more effectively to crush opposition to any future proposals to introduce the denominational element into University education in this country."

If, as is stated here, these appointments mean that the Belfast Medical School is left without a representative on the Council, we have no hesitation in expressing our opinion that the School has been treated unfairly.

#### Physical Culture.

ONE of the crazes at the moment is for physical culture, and various instructors in the art are kept busy teaching weakly youths and corpulent gentlemen how to attain the proportions of Apollo and the bloom of health by a few simple exercises. Far be it from us to deny that such a movement is both wholesome and health-giving, and far more desirable than many of the silly fashions that periodically seize people with more money than brains, and more imagination than common sense. The appetite for physical betterment has been carefully whetted by various devices, and physical culture schools are now among the most paying investments for brawny men with a modicum of brains. But as inevitably happens with all craftsmen who deal with the human body and who acquire a circle of clients, the temptation to leave the latter and enter into a wider sphere of practice has become too great, and these professors of physical culture have—some at least of them—yielded to it. One of the best-known of these teachers has lately taken large offices—and advertised

that he can treat dyspepsia, constipation, insomnia, and various other ailments by his method, and that this treatment can be carried on by correspondence, and so arranged that the sufferer can, at small cost and without interference with his ordinary avocations, effect the cure in his own bedroom. As medical men in the past have been disposed to look not unfavourably at the physical culture movement, and some have even sent patients for a course of exercise under its exponents, it behoves them to notice to what use their patronage has been put, and what its effect has been. In future we think they will be well advised to inquire into the methods adopted by any teacher they recommend, and to give a wide berth to those who, besides and beyond their legitimate business, advertise to treat and cure diseases. As the world wags every man seems to think himself endowed by Nature with the gift of healing, a delusion which the law assists by confining its attention to legally qualified practitioners of medicine, while a horde of quacks are allowed to prey on the public unhindered.

#### The Heart in Diphtheria.

THE poison of nearly all the acute specific fevers seems to focus itself with special intensity upon the vascular system and upon the heart in particular. The early and also the remote effects of typhoid fever upon the circulatory system are of great clinical importance, and scarcely less so are the various morbid conditions of the heart that may be met with in the course of true diphtheria. How many times has not a suddenly fatal collapse occurred during apparent convalescence from this disease simply owing to the slightly increased strain thrown upon the heart in the act, say, of sitting up in bed! Nor has cardiac weakness or actual organic disease always been a marked feature in such cases. Much may be learnt concerning the cardiac complications of diphtheria from a valuable communication by Drs. Franklin White and Howard Smith, (a) of Boston, U.S.A., who have made a study of 946 cases of this affection with special regard to its effect upon the heart. These observers have found that irregularity of the pulse occurred in 60 per cent. of all the cases, this being more marked in young patients. Of the cardiac murmurs which were present, the majority developed within the first few days of the illness, lasted several weeks, and in 78 per cent. they were present at the time of discharge. Acute, sudden cardiac dilatation was not common, all the fatal cases showing a gradual heart failure. Slowness of the pulse was rare, but extreme bradycardia often heralded a fatal issue. The most important sign of organic heart disease in diphtheria is stated to be the presence of the galloping rhythm, and following this, the appearance of vomiting is to be regarded as of ominous import. This latter symptom would seem to indicate vagus degeneration, and in a few cases this has been found *post-mortem* by Councilman. Frequent examination

(a) *Boston Med. and Sur. Journ.*, October 20th, 1904.

of the heart is necessary, and in all cases more or less prolonged rest in bed is advisable, especially when the pulse remains persistently rapid.

#### The Jubilee of Modern Nursing.

THE life of the present generation has been so completely in the age of scientific nursing that it is only the older among us who remember a time when the trained nurse was not. Her position is now so well established—second only to that of the medical adviser himself—that we find it hard to realise that it is only fifty years to a few days since the first band of English trained nurses was organised by Miss Florence Nightingale. In 1847 a request was published for nurses to volunteer for service in the Haslar Naval Hospital, but not a single volunteer appeared. In 1854, when the Crimean war had been some months in progress, it was borne in on the authorities that the sick and wounded soldiers were not receiving the care they should, and Miss Nightingale, who had some years before undergone a year's training at Kaiserswerth, was invited to organise a nursing service. She arrived with her band of thirty-seven nurses at Scutari on November 5th, 1854, and from that date begins modern English nursing. It would be waste of paper and ink to draw attention in detail to the revolution in the treatment of the sick which has taken place since then. The system inaugurated by Miss Nightingale has been the basis, not merely of every system of military nursing, but of the care of the sick as practised to-day in every civilised country. Of Miss Nightingale's life-long interest in the profession she created it is equally unnecessary to speak. Her donation of the testimonial presented to her by the nation in 1857 to the foundation of a training school for nurses in connection with St. Thomas's Hospital is merely one example of this interest. The medical profession is glad to join in congratulations to one to whom suffering humanity owes much.

#### A New Dental Journal.

WE are glad to notice the arrival of a weekly paper, the *Dental Surgeon*, devoted to the interests of the dental profession and the study of dental science. It is sure to meet a distinct want, for, however excellent may be a monthly or quarterly review, it contains a different kind of material, and calls for a different kind of reading from a weekly newspaper. The standard of education in the dental profession is being steadily raised in recent years, and the practitioner takes a wider interest in the doings of his fellows than formerly. A weekly paper which, in addition to articles of scientific value, gives in interesting fashion items of passing news, should appeal to a wide audience. It is of importance, too, that there should be a free medium for discussion on the various political questions which are of interest to our dental brethren. Even more than ourselves, they suffer from unqualified competition, and the competition of companies, while there are various

ethical questions, such as the permissibility of advertising, which have yet to be settled. The first number of our contemporary is bright and interesting, and we have pleasure in wishing our youngest contemporary a long and useful career.

#### The Surgeon's Post in French Duels.

THE recent disgraceful assault on General André, an old man, in the French Senate, has led to a crop of duels. Needless to say, these encounters were for the most part void of bloodshed, although by an unforeseen accident one of the combatants sustained a cut in the wrist. It is to be hoped that the wounded hero will treasure—for the rest of his life—the lesson gained by his bloody experience, so that in succeeding duels he may treat the cold steel of his adversary with distant respect, according to the fashion of his cooler-headed countrymen. An even more terrible experience awaited the surgeon in attendance at one of these duels. The fight was to be settled with pistols, and he stood midway between the duellists at what he thought to be a safe distance. At the first discharge both bullets whistled close to the head of the surgeon, who thereupon retired several yards further from the zone of fire. In vain, however, was his strategy, for on the next exchange of shots one cut through the brim of his hat and the other grazed his knee. The surgeon then beat a precipitate retreat from the field of battle. Clearly the safest plan for him, if he ever summons up enough courage to attend another duel, is to insist upon both duellists aiming at the surgeon. The medical profession is one of peace, and it would be a pity to deprive it of one of the few opportunities of figuring in warlike events by neglect of a few commonsense regulations that could readily be framed by anyone conversant with the French duel.

#### The Aldershot Poisoning Outbreak.

THE origin of the wholesale poisoning which took place last week at Aldershot still remains a mystery. A number of non-commissioned officers and men—according to some accounts not less than a hundred—of the Yorkshire Light Infantry, were attacked with sudden sickness and prostration, but we are glad to learn that all have made a rapid recovery, with the exception of a corporal, whose condition was at one time critical. The nature of the illness and the history of the outbreak point with unmistakable directness to the source of the mischief in some form of food-poisoning. Indeed, a circumstantial account has already been circulated in which the irritant has been traced to an Irish stew which the men had for dinner on Thursday last. It is said that those who ate roast meat, the alternative dish, escaped the attack. If the stew is proved to have been at fault, it still remains to be found out whether the case is one of ptomaine poisoning from bad meat, or one of contamination from metallic or unclean cooking vessels. The whole matter is to be sifted to the bottom by a Board of Officers summoned by the Principal Medical Officer to

investigate the affair. The rarity of occurrences of the kind go far to prove the absolutely careful supervision of food and of kitchens that must be in force in our great military camp at Aldershot.

## PERSONAL.

THE list of Birthday Honours includes the names of four members of the medical profession, upon whom the honour of Knighthood has been conferred by His Majesty the King.

PROFESSOR WILLIAM JAPP SINCLAIR, one of the recipients, the well-known Manchester physician, is fifty-eight years of age. He is M.A. and M.D. of the University of Aberdeen, and is at present Professor of Obstetrics in Manchester University. He withdrew from the Liberal Party in the Home Rule split in 1886.

DR. CHARLES HAYES MARRIOTT, J.P., another of the new Knights, began his connection with Leicester forty-four years ago by becoming house surgeon at the local Infirmary. He resigned the honorary surgeoncy of that institution in 1901.

SIR SHIRLEY MURPHY, as he now becomes, has long been prominent in public health work. Educated at Guy's Hospital, he became a member of the English Royal College of Surgeons in 1870. He has been Lecturer upon Public Health at St. Mary's Hospital School, and among other distinguished posts has been President of the Society of Medical Officers of Health. His most important post has been that which he now fills with distinction, namely, that of the Medical Officership of Health of the Administrative County of London.

MAJOR ALLEN PERRY, the fourth Knight, took his various medical degrees between 1884 and 1892. He was for three years at the Royal Westminster Ophthalmic Hospital, and was then junior house surgeon at the Poplar Hospital for Accidents, and a house physician at the London Hospital. His present positions are those of Principal Medical Officer and Inspector General of Hospitals of the Island of Ceylon.

At the opening meeting of the Aberdeen University Medical Society, at Marischal College, on November 4th last, an interesting address on "The Medical Student and his Profession" was delivered by Mr. J. Scott Riddell, senior surgeon of the Aberdeen Royal Infirmary.

PROFESSOR CASH, F.R.S., on the 3rd instant, delivered his presidential address to the Aberdeen Medico-Chirurgical Society on the subject of dosage.

DR. E. H. TAYLOR has been appointed assistant to Professor E. H. H. Bennett, who now fills the Chair of Surgery in the School of Physic, Trinity College, Dublin.

A CIRCULAR letter, signed by a large number of influential medical men, has been issued in support of the candidature of Sir Henry Craik for the Parliamentary representation of the Universities of Glasgow and Aberdeen.

DR. JAMES BRISBANE will preside at the annual dinner of the Glasgow University Club in London, on the 23rd instant. Further particulars can be obtained of the Honorary Secretaries, 63 Harley Street, W.

THE distinguished recognition of a royal medal has been conferred by the Council of the Royal Society upon Colonel David Bruce, R.A.M.C., F.R.S., for his researches and discoveries in the causation of various tropical diseases.

PROFESSOR JOHN MCFADYEAN, M.B., B.Sc., Principal of the Royal Veterinary College, will deliver the Harben

Lecture on Glanders at King's College, 5 p.m., November 25th and December 9th. Members of the medical profession are invited.

DR. W. WATSON GLENNY, of Omeath, has been appointed to the magistracy of county Louth, and Dr. John McFadyean to a magistracy of Govan.

MR. ARTHUR H. TREVOR has been appointed Secretary to the Commissioners in Lunacy in the place of Mr. L. L. Shadwell, who has been appointed a Commissioner in Lunacy.

DR. A. D. CLINCH, of Clondalkin, has been elected President of the Irish Rugby Football Union. He is an old International player, and sometime captain of the Dublin University Football Team.

DR. T. GREGORY FOSTER, B.A., Ph.D., principal of University College, London, has been elected a representative of the College on the Senate, in the place of Dr. G. Carey Foster, resigned.

MR. H. T. BUTLIN, D.C.L., F.R.C.S., has been elected a representative of the Royal College of Surgeons of England on the Senate of University College, London, in the place of Sir Henry Howse, resigned.

DR. BASIL M. WILSON has entered the Civil Service of Fiji as a Government Medical Officer.

MR. CURTIS C. A. JONES has taken up duty as a Medical Officer of Lagos. He acts as an assistant in the general and medical sanitary work of Lagos town.

THE British Chaplain at Berlin, the Rev. J. H. Fry, recently opened a private hospital which has been founded on behalf of English and American patients desirous of receiving more individual nursing than that obtainable in the Berlin hospitals.

THE Committee of the Bristol Lunatic Asylum have appointed as the new superintendent in place of the late Dr. Benham, Dr. James Vincent Blachford, who has been assistant medical officer since 1896.

WE understand that Dr. W. H. Hamer has been selected as head of one of the branches of the London County Council public health department at a salary of £850, rising to £1,000, and an assistant medical officer will be appointed in place of Dr. Young, who has resigned.

THE King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Dr. W. Leslie Mackenzie to be the medical member of the Local Government Board for Scotland, in room of Dr. Russell, deceased.

THE funeral of Dr. Vintras, principal physician of the French Hospital in London, will take place at the Church of Notre Dame de France. The French Ambassador will be present.

MRS. NOSWORTHY, of Newlands, Dawlish, has offered to defray the whole cost (estimated at ten thousand pounds) of the erection of a new operating theatre at the Royal Devon and Exeter Hospital at Exeter.

DR. R. H. FLEMMING has been appointed to the post of Gynæcologist to the Royal City of Dublin Hospital, in succession to the late Dr. J. L. Lane.

## The Mater Misericordiae Hospital, Dublin.

THE medical session at this hospital was formally opened on the 8th inst., when an interesting address was delivered by Sir Christopher Nixon, M.D., on "The Various Phases of a Hospital's Work." The address will be found in another column.

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND,

**PARLIAMENTARY REPRESENTATION OF THE UNIVERSITIES OF GLASGOW AND ABERDEEN.**—The Glasgow University Conservative and Liberal Unionist Association and the Aberdeen Unionist Association have issued a circular, dated November 8th, in reply to that recently referred to in this column, sent out by the Universities of Glasgow and Aberdeen Conservative and Liberal Unionist Association in support of the candidature of Professor W. R. Smith, M.D., who is opposing Sir Henry Craik, the official nominee of the party associations. The new circular states that Sir Henry Craik's nomination was decided on after careful consideration of both committees, on which the medical profession is largely represented. Sir Henry Craik was a Snell exhibitioner, and after leaving Glasgow University, went to Balliol College, gaining high honours at Oxford. In 1882, he was made LL.D. of Glasgow. His life has been devoted to educational work, first in the English Education Office, and subsequently as secretary to the Scottish Education Department, from the year 1885 (in which it was established) until the present time. His "recognised position as a man of letters, and his unique experience of the working of educational systems both of Scotland and England, peculiarly qualify him to represent a University constituency." Sir Henry Craik's Committee contains the names of a number of the medical profession, among others those of Sir Wm. Gairdner, Sir Hector Cameron, Sir Wm. MacEwen, Drs. McCall Anderson, Mitchell Bruce, Cossar Ewart, Freeland Fergus, David W. Findlay, Matthew Hay, Yule Mackay, T. G. McKendrik, and Samson Gemmel.

**AGE LIMIT FOR THE STAFF OF THE EDINBURGH ROYAL INFIRMARY.**—The special Committee appointed to deal with this question has just issued a long report which was submitted to the Court of Contributors on the 14th inst. We may recapitulate shortly, from the report, the circumstances which led to the appointment of the Committee. Towards the end of 1903, the managers of the Infirmary decided that the ordinary physicians and surgeons should be retired at the age of sixty-five, the rule not to apply to those serving their second or third term of five years in charge of wards nor to Professors. When this rule came before the Court of Contributors for confirmation, a motion was carried putting the professors on the same footing as the ordinary staff, but at the adjourned meeting this was in effect overthrown by the appointment of a committee to confer with a committee of the managers, and to report. This special Committee met on several occasions, and now report as follows:—The clerk of the Royal Infirmary made an exhaustive search through the minutes of the Infirmary, and prepared excerpts therefrom as to the relationship of the University and Royal Colleges to the Infirmary. These were printed and circulated to all interested parties, and it may be here stated that they indicate clearly that the professors hold their wards at the pleasure of the managers, and not under any right or agreement, and this has been admitted by the senators in a subsequent communication to the Committee, but hitherto professors have retained the charge of wards without question, so long as they continued to occupy their chairs. In reply to requests for an expression of their views on the subject, the Royal College of Physicians, the Royal College of Surgeons, and the Staff of the Infirmary favoured an age limit; the University was against it. The Committee then ascertained the rules and practice regulating the appointment of the ordinary staff, the number of wards and beds under the care of each member of the staff, the dates of appointment as assistants of the members of the ordinary staff, and of their subsequent promotion to full rank; and the dates of appointment of the present assistant staff. Having fully considered the whole question, the Committee think that a compulsory age limit is inexpedient, and

recommend (1) that the rule fixing an age limit be not adopted, (2) that accordingly the resolution requiring professors to retire at the age of sixty-five be rescinded, and (3) that in future each Professor and physician and surgeon in charge of wards may, on the expiry of his appointment, apply for reappointment, when the managers shall give careful consideration to his case, and when, if the managers deem it expedient, he may be reappointed for such term as they may fix. These recommendations will, the Committee think, render an age limit superfluous. In the case of the ordinary staff, an age limit of sixty-five, looking to past experience, would practically never become operative. Under the proposed rule the managers will have the special control of the duration of office of members of the staff, and professors, and will have it in their power to renew for five years, or less, or to resolve that there shall be no reappointment. The report, of which the gist is given in the preceding, is signed by eight members of the Committee. Two members dissent from the foregoing conclusions and recommendations, on the ground that in the interests of the patients and of medical and surgical science an age limit is desirable. It is to be presumed that the whole matter is now settled, though it awaits final confirmation of the meeting of the contributors.

### BELFAST.

**THE SMALL-POX EPIDEMIC.**—During the last fortnight nine more cases of small-pox have been discovered, and removed to the hospital at Purdysturn. Of these only one appears to be severe, the patient being a man of forty without vaccination marks or history of vaccination. Two cases have died during the fortnight—one an unvaccinated child, and the other a man of thirty-seven, said to have been vaccinated, but on whom no marks could be found. It is rather amusing to note that the present has been chosen as an appropriate time for an anti-vaccination campaign in Belfast. A series of meetings has been held during the past week, at which an imported lecturer has harangued small audiences, generally under the chairmanship of a member of the Board of Guardians. To judge from appearances, not much harm is likely to be done. The Belfast public has always got a fair amount of excitement out of its religion and politics, and has never taken kindly to the numerous fads which flourish so luxuriantly across the Channel.

**THE ULSTER MEDICAL SOCIETY.**—The opening meeting of this Society was held in the Medical Institute, Belfast, on Thursday evening, November 9th. Dr. John Campbell, who has been president for the past two years, having introduced his successor, Dr. William Calwell and vacated the chair, received a hearty vote of thanks, on the motion of Professor Symington, seconded by Dr. Hadden (Portadown). Dr. Calwell delivered an address on "Some Aspects of Metabolism, chiefly Clinical," which will appear in a subsequent issue of this journal. At the conclusion of the address, a vote of thanks was moved by Dr. J. Walton Brown, and seconded by Professor Lindsay.

The report of the Council stated that the annual dinner has been arranged for Saturday, December 3rd, when Sir Lauder Brunton will unveil the bust of Sir William Whitla, which has been executed for the members of the Society by Miss Kathleen Shaw. A number of guests from Dublin and from across the Channel are expected to be present.

## Correspondence.

### LOCAL SUPERVISION OF CERTIFIED MIDWIVES.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*  
SIR,—The success of the Midwives Act of 1902 greatly depends upon the efficiency of the supervision of the local supervising authorities appointed by the Councils of the Counties and County Boroughs throughout England and Wales, and also upon local efforts for assisting the midwives to acquire the knowledge

which is essential for the correct discharge of their new duties.

Up to the present time the midwives throughout the land have been carrying on their work without any restrictions, and it is a fact that the greater part of these women have never received any instruction or training, and are in every sense incapable and ignorant of their responsibilities. I have often been told by my medical brethren that many women who have been acting as midwives for years, and who have recently obtained certificates under Section 2 of the Act, do not understand that they are under strict local supervision and control, and that in every difficulty and in every deviation from the normal they are bound to send for professional assistance.

Now there must be urgent need, if these statements are true, for the development of a scheme to assist the existing midwives to learn their new duties, and to work in conformity with the provisions of the Midwives Act. Without help it is impossible for them to reach a standard of knowledge equal to their responsibilities. But how is this assistance to be provided? Surely it is a question which demands the serious consideration of all local supervising authorities, and there can be no doubt that in every large centre it will be easy for the local authorities to secure means for the enlightenment of the women placed under their control. Without such help, it will not be possible to speedily clear the lying-in-room of the ignorance, superstition, and sanitary impurity which have been the cause of the terrible mortality among the poor parturient women of our country. The instruction in elementary topics would prove a great boon to practising midwives, and it could be given by lectures, by oral examination, and by exhibiting the method of reporting the details of practice and of carrying on the work in accordance with the rules framed by the Central Midwives Board. I believe that in every area medical practitioners will be found willing to assist the local supervising authorities in this important object.

I have read with much pleasure the able address of Dr. Ewen Maclean, which he delivered at the University College, Cardiff, on the Education of Midwives, and I wish a copy of this valuable lecture could be sent to all the members of the County Councils throughout the country.

I am, Sir, yours truly,

J. WARD COUSINS,  
Representative of the R.C.S. of England  
on the Central Midwives Board.

November 8th, 1904.

#### INOPERABLE CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
SIR,—I beg to say that the abdominal case noted by Dr. J. A. Shaw-Mackenzie, in his paper, "On the Treatment of Inoperable Cancer by Hypodermic Medication," in THE MEDICAL PRESS AND CIRCULAR, October 19th, has been under my care, and I can so far corroborate the results obtained with the hypodermic injections of Chian turpentine I have given.

I am, Sir, yours truly,

FRANK BOXALL.

Rudgwick.

#### CHLOROFORM ANÆSTHESIA.

To the Editor of the MEDICAL PRESS AND CIRCULAR.  
SIR.—In an editorial article, November 9th, headed "Chloroform Anæsthesia," you refer by name to me, and after mentioning that I have used the Vernon Harcourt chloroform inhaler with success in some hundred cases, you add "as far as we know, no details of them (the cases) have yet been made known, and it was more than hinted in the Oxford discussion that there were others in which he had not been so fortunate." Allow me to say it is quite untrue that any suggestive hint or more than hint was made publicly at the Oxford discussion in reference to cases of anæsthesia under chloroform conducted by me; had there been it would at once have been answered.

All my cases have been noted, and in no single case has death or any dangerous symptom due to chloroform arisen. Any hint or "more than hint" suggesting such death or dangerous symptom is devoid of all truth.

I am, Sir, yours truly,  
DUDLEY W. BUXTON.

London, W., November 14th.

### Literary Notes and Gossip.

MESSRS. LONGMANS, GREEN AND Co. will publish next month a "Text-book of Medical Practice," by various contributors, edited by Dr. William Bain. Apart from the practical character of the book, the special features are that the anatomy, histology, and physiology of each organ or system precede the description of the diseases, and that the various sections are contributed by general physicians and specialists.

\*\*\*

MESSRS. BAILLIÈRE, TINDALL, AND COX will publish next week, in their popular "University Series," the ninth edition of Dr. Macnaughton-Jones' "Manual of Diseases of Women." This book has met with a success almost phenomenal, and the new edition is announced to contain between six and seven hundred coloured and plain plates and other illustrations, the text being revised to date, and all the latest British, Continental and American methods in gynecology portrayed.

\*\*\*

AN important addition to the literature of Cities and of Civics has just been made by Messrs. Geddes and Co., of Edinburgh and Westminster, and the St. George's Press, Bourneville, by the issue, on the 10th inst., of "City Development, a Study of Parks, Gardens, and Culture Institutes; a Report to the Carnegie Dunfermline Trust," by Professor Patrick Geddes, at 21s. net. Professor Geddes has approached his task of designing the improvement of a city at once with local survey and with general ideas, and thus his book will be found to appeal to citizen and city improver, municipal councillor and official, architect and gardener, educational and social worker, &c., to antiquary and to Nature-lover also.

\*\*\*

THE term "fever" embraces so many illnesses, from mumps to typhus and yellow fever, that a book such as the "Manual of Fever Nursing," shortly to be issued by Messrs. Kegan Paul, of Dryden House, should prove useful. It is written by Professor Webb Wilcox, and deals exhaustively with fevers, their causes and symptoms, and their treatment in accordance with the present state of practice. The clinical charts and directions for nursing suitable for different cases should make this a valuable handbook for nurses.

\*\*\*

"LETTERS on Health and Happiness" is the title of a little work by John A. Bevan, M.D., Torquay. No one can say that at the present there is a lack of counsellors in regard to matters relating to personal and public hygiene, but although knowledge comes, wisdom lingers, and even though the path to heaven be paved with good intentions, happiness is by no means assured. Dr. Bevan, in these well-intentioned letters, tells us that his object is to remove suffering, to restore health and strength, to prevent irremediable organic disease, and to prolong the blessing of a cheerful mind in a healthy body to a genial longevity. There is much information unconventionally expressed in these unpretentious pages, and although we cannot endorse much of the pathology, we cordially admire the spirit which has prompted the publication of these life lasters.

\*\*\*

ANOTHER professional journal has been launched during the last few days by the energy of its publishers, Messrs. Baillière, Tindall, and Cox, entitled the

**Dental Surgeon.** Hitherto the dental section has been catered for by two or three monthlies, but, like all other professions, the dental has strongly expressed its desire for a more frequent medium of inter-communication, which has now been met. We have the first two weekly numbers before us, edited by Mr. Robert Manning, who will be assisted by a considerable number of dental surgeons, the majority of whom are attached to the dental schools and hospitals in the leading centres of the United Kingdom. These initial numbers are distinctly creditable, both to the editorial staff, and to the publishers, and if future issues can be maintained at such a high standard, no prophetic acumen is needed to foretell the chances of such a publication. Our new contemporary has our best wishes.

### Obituary.

ACHILLE VINTRAS, M.D. SCOTLAND, M.R.C.S. — ENGLAND.

THE news of the death of the senior physician of the French Hospital and Dispensary will be received with regret by a large circle of friends and acquaintances. After a long and busy life, Dr. Vintras died on the 9th inst., at Brighton, at the age of seventy-five. His medical education was conducted at St. Mary's Hospital, and in Paris. In 1858 he became M.R.C.S. of England, and the year after he took the degree of Doctor of Medicine of St. Andrews University. He was an Officer of the French Legion of Honour, and Physician to the French Embassy in London, as well as holding many other distinguished posts. His death, which took place in the French convalescent home he directed at Brighton, will be greatly felt by the French colony in London, in which he has been for so many years a prominent figure. Dr. Vintras' literary contributions were principally confined to books and papers on the Mineral Waters and Health Resorts of France, his other essays being two small pamphlets on "The Treatment of Diabetes" and "Animal Vaccination."

DONALD M'LEOD, M.D. GLASGOW.

WE regret to announce the death of Dr. Donald M'Leod, who has earned the title of father of the medical profession in Kilmarnock. He died at his residence on the 9th inst., aged 83. He had practised in the town for fully half a century, but retired about eighteen months ago. For a long period he was medical officer to the Parochial Board and Parish Council. He was a physician of exceptional skill. His medical education was conducted at Glasgow University, where he took the degree of M.D. in 1850.

DR. C. D. F. PHILLIPS.

WE regret to record the death, at 1 Hyde Park Square, London, on Sunday last, the 13th inst., of Dr. Charles Douglas Fergusson Phillips, late of Henrietta Street, Cavendish Square, W., at the age of 74. Dr. Phillips qualified in 1852, and was M.D. Aberdeen, LL.D. Aberd., LL.D. Edin., F.R.C.S. Ed., F.R.S. Ed., M.R.C.P. Lond., and Hon. Fellow of the Medico-Chirurgical College of Pennsylvania. He was at one time Lecturer on *Materia Medica* and Therapeutics at the Westminster Hospital, London, and subsequently Examiner in these subjects in the Universities of Edinburgh, Glasgow, and Aberdeen. He was the author of a well-known work on *Materia Medica*, the third edition of the first volume of which was published only a few months ago. He had retired from practice, and was the Chairman of the Universities of Glasgow and Aberdeen Liberal Unionists' Association. The immediate cause of death was the Stokes-Adams syndrome, and he was attended in his last illness by his old friend and colleague, Dr. Murrell.

### Medical News.

#### Medical Aid to Seamen.

IN response to a request made by the Missions to Seamen, Messrs. Burroughs Wellcome have given that Society a case of tabloid medicines, with a copy of their "Brief Medical Guide for Explorers, Missioners, etc.," to be used only in circumstances outside the reach of medical aid. They were given as outfit for the Bristol Channel Mission steamer *Eirene* in her visits to lightships and other vessels in the outer anchorages for use by the Roadstead Chaplain of the Missions to Seamen.

#### Entrance Scholarships: Westminster Hospital Medical School.

THE examinations for the entrance scholarships at this school have resulted as follows: Epsom Scholarship of 110 guineas, Mr. H. F. R. Davison; University Scholarship of 40 guineas, Mr. R. W. Ironside. Natural Science Scholarship of 60 guineas, Mr. H. S. Hingston; Governors' Scholarship of 40 guineas, Mr. W. R. Asplen; First Scholarship in Arts of 60 guineas, Mr. C. G. Richardson; Second Scholarship in Arts of 30 guineas, Mr. H. Evans; Science Scholarship of 40 guineas, Mr. A. O. Mitchell.

#### The New President of Queen's College, Cork.

THE more than enthusiastic reception which the newly-elected President of the Queen's College, Cork received on his arrival at his new sphere of duty should be a sufficient answer to those of our contemporaries who openly stated that his election was the result of a political job, and that the President would not be favourably received in Cork. Professor Windle was met on his arrival at the railway station by a procession of some three hundred students, who loudly cheered him. Mr. J. Horgan, a leading Cork citizen, introduced the more senior of the students to the President and presented Mrs. Windle with a bouquet of flowers. The following address of welcome was then read:—Address from the Students of the Queen's College, Cork, to Bertram C. A. Windle, Esq., F.R.S., D.Sc. F.S.A.

Dear Sir.—We, the students of the Queen's College, Cork, tender to you a thousand welcomes to our city. Your appointment to the high and honourable position of President of our College has given pleasure not only to us whose lives are spent within its halls, but also to great numbers of thinking Irish people, who are glad to recognise in you a worthy representative of the better system of government which is happily beginning to prevail in many spheres of national life. We recognise that you are a fellow-countryman by every claim that a man can urge to be called such. You have shown a deep interest in the language and glories of the ancient Gael, and we would suggest that here, in the heart of the great province of Munster, you will find scope for renewed efforts in the cause of intellectual and national regeneration. We are well aware of your brilliant literary attainments, and in these days, when too many people abandon themselves to the pursuit of a solitary subject and lose, in the fastnesses of the museum or the dissecting chamber, those qualities necessary for the civilised intercourse of life, we rejoice to meet with one who, as you, leaps the barriers of anatomy and wanders away to the sunnier regions of archaeological and Shakespearian research. We trust, then, that under your presidency Queen's College, Cork, may continue with ever-increasing vigour, the great work of professional education which it has so long carried out, and we again wish you welcome and prosperous days in this "Faire Citie" of the South.—Signed on behalf of the Students,

Faculty of Medicine—W. C. T. Robey, M. White, J. C. Hart, T. P. Sheedy, E. Forbes;

Faculty of Engineering—Arthur Ridge, Thomas J. Waters;

Faculty of Arts—D. L. Kelleher, David Horgan. After reaching the College quadrangle, the President made a short speech to the students, in the course of

which he testified to his pleasure at having returned to his native country. The proceedings then terminated amidst renewed cheering.

#### Catholic University Medical School.

*Medical and Scientific Society, Session 1904-5.*—The following officers have been elected for the ensuing session: President, Professor Antony Roche; Hon. Secs. and Treasurer, A. N. M'Loughlin, O'Connell O'Sullivan, J. B. Butler; Committee, Professor D. J. Coffey, Professor E. J. M'weeney, Dr. Dargan, Dr. M'Loughlin, Dr. Blayney, Dr. O. Farnan, F. J. Madden, R. Slattery, T. T. O'Farrell, W. R. O'Farrell, J. Elwood, W. P. Dunne. The inaugural meeting will take place at the Medical School, Cecilia Street, on Thursday, November 24th, when the President will deliver an address.

#### Diphtheria Outbreak in Ireland.

An epidemic of diphtheria has broken out in the Drumlish dispensary district, Co. Longford, and twenty-four deaths from the disease have occurred.

### PASS LISTS.

#### Queen's College, Galway.

The following scholarships and exhibitions have been awarded by the Council:—

*Faculty of Medicine.*—*Senior Scholarship in Anatomy and Physiology:* John L. Dunlop, B.A. Fourth Year: Scholarship, James J. A. Gannon; Exhibition, Joseph M. A. Costello. Third Year: Scholarships, John Hughes, Christopher F. X. O'Sullivan; Exhibitions, Joseph D. G. Burke, Richard G. C. M. Kinkead, John W. Garry. Second Year: Scholarships, Edward Dowling, Michael J. Mulligan; Exhibition, George Deery. First Year: Literary Division, Scholarships, Michael G. Devine; Exhibitions, Bartly Byrne, Michael G. O'Malley; Science Division Scholarships, Thomas G. Rothwell; Exhibitions, James A. Brown, Jame M. Riorth.

#### Trinity College, Dublin.

MICHAELMAS TERM, 1904.

*Previous Medical Examination.*—*The following passed in Anatomy and Institutes of Medicine:*—Henry J. Keane, Henry D. Woodroffe, Albert J. T. M'Creery, John C. Baker, Francis O'B. Kennedy equal; Langford V. Hunt and James G. G. Moloney, equal; Henry P. Hart, Herbert Allport.

*Physics and Chemistry:*—Arthur H. Laird, John Gray and Julian B. Jones, equal; William E. A. Moore, Wellesley R. Allen, Richard D. Fitzgerald, John H. Morton, equal; Cecil J. Grene, Henry R. Kenney, James D. K. Roche.

*Botany and Zoology:*—Henry de C. Dillon, Harold S. Sugars.

*Previous Dental Examination.*—*Anatomy and Institutes of Medicine:*—Charles R. Kidd, Arthur K. Macdonald.

*Materia Medica:*—Charles R. Kidd.

#### Royal College of Surgeons in Ireland.

The Carmichael Prize of £120 for the best essay "On the State of the Medical Profession in its Different Departments" has been awarded by the College to Dr. Michael Foster Reaner.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 2nd inst., with the following results:—

*Final Examination.*—Of eighty-four candidates entered, the following thirty-eight passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—Joseph van Someren Taylor, China; Henry Lawrence Ludovici, Colombo; John Roddick Byers, Canada; Stuart Evans, Ottawa; William Murray, Middlesbrough; John Browne Grogan Mulligan, Belgium; James Francis O'Mahony, co. Cork; Ernest Temple Curran, Ontario; Thomas Cassels, Mangalore; James Patrick Barry, New Zealand; Geo. Galen Bartholomew, Scotland; Carel Theodorius Möller, South Africa; John Michael Moriarty, Ireland;

Samuel Mortimer Lyon, Ontario; James Ringland Lawther, co. Down; Damadar Babaji Mandhle, Bombay; Maneckji Pirozshah Kerrawalla, Bombay; Colin Garner, Preston; Lilian Mary Grandin, Jersey; James Harvie, Lesmahagow; John Pringle Tolmie, Inverness; Harvey McKay, Toronto; Alan Cunliffe Vidal, Eton; Ruston Nusserwanji Coorlawala, Satara; Robert Wilfrid Simpson, Glasgow; James Joseph Egan, Galway; Mohamed Ebrahim Sufi, Lucknow; Rowland Hill Harris, Maine, U.S.A.; Henry Bentley, Manchester; William Dick, co. Tyrone; John Douglas Staley, Youlgreave; Thomas Alexander Wiltshire Walker, Hyderabad; Edwin Herbert Freeze, Canada; Timothy Archdeacon, co. Cork; James William McEwan, U.S.A.; Walter Longley, Leeds; Kashibhai Vaghajibhai Amin, Ahmedabad; and John Black Moffatt, Airdrie; and ten passed in the division of medicine and therapeutics; three in surgery and surgical anatomy: six in midwifery, and six in medical jurisprudence.

#### Royal College of Physicians and Surgeons.

CANDIDATES have passed as undernoted:—

*Third Professional.*—*Passed in all subjects:* A. P. Barrett, M. D. Healy, C. W. O'Keefe, John Prendiville, C. H. Waddell, and Rupert Welply. *Completed examination:* L. A. Andrews, C. J. Bergin, T. S. Blackwell, John Burke, W. J. Connolly, R. F. O'T. Dickinson, T. A. Fisher, Cormac Gordon, J. J. Hogan, John M'Quillan, William Roche, William Sheahan, Edmund Smith, J. R. Talbot, N. R. Ussher, J. J. Vasquez, and G. F. Wright.

*Final Examination.*—*Passed in all subjects:* J. R. P. Allin. *Completed Examination:* Michael Ambrose, E. C. Byrne, H. A. Cecil, Selby Clare, F. X. Costello, H. B. Evans, P. E. Harrison, M. C. O. Hurly, E. C. Jennings, R. W. D. Leslie, M. J. Lochrin, V. H. MacSwiney, E. C. Mulligan, J. C. Murphy, T. J. O'Donnell, B. H. Peters, John Pratt, S. H. Robinson, A. J. Swanton, and Edmond Walsh.

*Supplemental Preliminary Examination, Autumn, 1904.*—Candidates have passed this Examination as undernoted:—*With honours:* O. W. J. Wynne. *Passed:* J. V. M. Byrne, C. P. Corbett, E. J. Curran, Thomas Duncan, L. M. Ewart, Charles Greer, Joseph Marmion, H. S. Meade, John Menton, Rodk. O'Connor, R. S. White, and W. H. Wray.

#### Conjoint Examinations in Ireland.

CANDIDATES have passed this examination as undernoted:—

*First Professional.*—*Passed in all subjects:* James J. Barry, A. H. T. Warnock. *Completed examinations:* Stephen J. Barry, J. Brereton-Barry, Thos. G. Brown, Noel M. Herbert, L. C. Johnston, H. G. M. Miles, K. A. P. R. Murray, Joseph McDonagh, D. S. MacDowell, Pierce Noonan, Martin C. O'Hara, Richard P. Power, F. Blood Smyth, and Bernard Wallace.

*Second Professional.*—*Passed with honours:* John Molyneux, J. F. Walsh, John McNamara, Patrick J. McKeveell, Charles J. B. Dunlop. *Passed in all subjects:* H. C. Burbidge, M. Beauchamp Dooley, R. de S. B. Herrick, A. A. Murray, Patrick J. Murray. *Completed Examination:* William Carroll, A. L. Clarke, James Joseph Clarke, James J. Corr, George A. Francis, Stanislaus A. Furlong, John Holmes, J. P. O'Kane, W. Roche O'Farrell, William A. Ryan, James V. Sage, G. B. Spencer, and Lionel D. Woods.

The Bishop of Durham has delivered judgment in the appeal by Miss Cadell, a lady doctor practising in London, against the decision of the warden of the University refusing to permit her to sit for the final examination in medicine at Durham. Dr. Cadell had previously failed in this examination and had in letters made allegations of favouritism and partiality against the examiners. The University authorities thereupon refused to permit her to sit again. She appealed to the Bishop, who is Visitor of the University. He decided that her letters were offensive and a breach of University discipline. He, therefore, upheld the warden's decision and dismissed the appeal.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and void the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS**.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**H.S. (Crewkerne)**.—"Suet," properly speaking, is obtained from the abdominal fat of the sheep, purified by melting and straining. It is used for preparing mercurial ointment. It consists chiefly of stearine and differs in various points from beef suet.

### DEATH AT THE CARD TABLE.

WHILE playing at cards with his son-in-law, Simpson Jacobi eighty-one, a retired shipping agent, of Shepherd a Bush, suddenly dropped the cards and died. At the inquest last week it was stated that death was due to the rupture of an aneurysm in the aorta, caused probably by excitement. In former times this would infallibly have been alluded to as a visitation of Providence.

A **BIRMINGHAM STUDENT**.—The constancy and inconstancy of employment necessarily affects the prevailing rate of wages. Higher wages are required to keep a man employed only part of his time. That general rule, however, does not apply to the "part time" Medical Officer of Health, because his income is derived mainly from general practice. He can thus afford to take less than the average standard salary due to a public health post—and gives less in return.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 16th.

**ROYAL MICROSCOPICAL SOCIETY** (20 Hanover Square, W.).—8 p.m. Paper.—Mr. A. E. Conrady: Theories of Microscopic Vision. (A Vindication of the Abbe Theory.)

**ROYAL METEOROLOGICAL SOCIETY** (Institution of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m. Papers.—Lieutenant C. Boyds, R.N.:—Meteorological Observing in the Antarctic. Mr. F. J. Brodie: Decrease of Fog in London during Recent Years. Mr. E. L. Holmes: Hurricane in Fiji, Jan. 21st-22nd, 1904.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.). 4 p.m. Mr. L. Cheate: Clinique. (Surgical.) 5.15 p.m. Mr. F. C. Wallis: Injuries to and Diseases of Joints.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (North-Eastern Fever Hospital St. Ann's Road, N.).—2.30 p.m. Dr. H. Cuff: Demonstration on Fever.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road W.C.).—5 p.m. Demonstration:—Mr. S. Low: Oro and Laryngopharynx.

THURSDAY, NOVEMBER 17th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. C. T. Williams: The Principles of Treatment of Pulmonary Tuberculosis.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. F. P. Weber: Climates and Health Resorts in the Treatment of Pulmonary Tuberculosis. (Post-Graduate Course.)

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture:—Dr. Chappel: Clinical Medicine.

FRIDAY, NOVEMBER 18th.

**SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN** (11 Chandos Street, W.).—5.30 p.m. Cases will be shown by Dr. J. Taylor, Mr. J. H. Evans, Mr. D. Drew, Dr. J. P. Parkinson, Mr. S. Stephenson, and Dr. H. Campbell. Specimens will be shown by Dr. B. Rogers, Dr. J. M. Fortescue-Brickdale, Dr. G. Carpenter, Dr. S. Curl, and Mr. D. Drew.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. E. Clarke: Clinique. (Eye.)

MONDAY, NOVEMBER 21st.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital).—4.30 p.m. Lecture: Mr. Cantlie: Liver Abscess and its Treatment.

TUESDAY, NOVEMBER 22nd.

**THERAPEUTICAL SOCIETY** (Apothecaries Hall, E.C.).—4 p.m. Dr. G. Sharp on *Strychnos Toxicaria Benth* and other Paralyzers of the Motor Nerve Ending.

## Vacancies.

**County Asylum, Mickleover, Derby**.—Junior Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

**Leeds Union**.—Assistant Medical Officer. Salary £120 per annum, with board, washing, apartments, and attendance. Applications to James H. Ford, Clerk, Poor-law Offices, South Parade, Leeds.

**Manchester Corporation**.—Medical Officer. Salary £250 per annum. Applications to the Chairman of the Midwives Supervising Committee, Public Health Office, Town Hall, Manchester.

**Wakefield West Biding Asylum**.—Assistant Medical Officer. Salary £140 per annum, with apartments, board, washing and attendance. Applications to the Medical Director.

**University of Birmingham (Faculty of Medicine)**.—Professor of Anatomy. Salary £800 per annum. Applications to Geo. H. Morley, Secretary.

**Braconbridge Asylum, near Lincoln**.—Junior Assistant Medical Officer. Salary £125 per annum, with furnished apartments, &c. Applications to W. T. Page, Jun., Solicitor and Clerk to the Visiting Committee, 5 Bank Street, Lincoln.

**Bermondsey Parish**.—First Assistant Medical Officer. Salary £17 per annum, together with rations, washing, furnished apartments, and attendance. Applications to E. Pitts Fenton, Clerk, Guardians' offices, 283, Tooley Street, S.E.

**Macclesfield General Infirmary**.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Chairman of the House Committee.

**Gloucester General Infirmary and Eye Institution**.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary.

**Manchester Royal Infirmary**.—Resident Surgical Officer. Salary £150 per annum, with board and residence. Applications to W. L. Saunderson, Superintendent and Secretary.

**Holloway Sanatorium Hospital for Insane** Virginia Water, Surrey. —Junior Assistant Medical Officer (Lady). Salary £150 per annum with board, lodging, washing, attendance, &c. Applications to Dr. W. D. Moore, Medical Superintendent.

**Leicester Infirmary**.—House Surgeon. Salary £100 per annum, with board, apartments, and washing. Applications to Harry Johnson, House Governor and Secretary, the Infirmary, Leicester.

**Monkstown Hospital**.—Resident Medical Officer. Salary £40 per annum. Applications to the Hon. Secretary. (See Advt.)

**County Mayo Infirmary**.—Assistant Surgeon, also to act as Compounder. Salary £109 per annum, with apartments, attendance, &c. Applications to Dr. M. O'Malley Knott, Resident Surgeon. (See Advt.)

## Appointments.

**BABST, C. T. U.**, L.R.C.P., L.R.C.S. Edin., Certifying Surgeon under the Factory Act for the Wallsend District of the county of Northumberland.

**BARNES, FRANK, M.B.**, B.S. Lond., F.R.C.S. Eng., Honorary Surgeon to the Royal Orthopedic and Spinal Hospital, Birmingham.

**DAVIS, WILLIAM HENRY, M.B.**, B.Ch. B.U.I., House Surgeon to the Royal Victoria Hospital Belfast.

**FORTUNE, JOHN, M.B.**, C.M. Edin., Third Assistant Medical Officer to the Devon County Asylum.

**GIFFORD, GEORGE T.**, M.D. Durh., M.R.C.S. Eng., Honorary Assistant Surgeon to the Blackburn and East Lancashire Infirmary.

**INGLIS, D.W.**, M.D. Glasg., Certifying Surgeon under the Factory Act for the Jarrold District of the county of Durham.

**LATHAM, W.**, L.R.C.P., F.I. M.R.C.S. Eng., Certifying Surgeon under the Factory Act for the London and North Western Railway Company's Works at Earlestown, in the Newton-le-Willows District of the county of Lancaster.

## Births.

**CLEVELAND**.—On Nov. 9th, at Norwich, the wife of A. J. Cleveland, M.D. Lond., M.B.C.P., of a daughter.

**DUNLOP**.—On Nov. 18th, at 38 Chester Street, Edinburgh, the wife James Crauford Dunlop, F.R.C.P. Edin., of a son.

**HENRY**.—On November 18th, at Debenham, Suffolk, the wife of Howard Henry, M.B., of a son.

**MALCOLM**.—On Nov. 11th, at 18 Portman Street, London, W., the wife of John D. Malcolm, F.R.C.S. Edin., of a son.

## Marriages.

**BLACKER—BOWEN**.—On Nov. 8th, at St. Mary's Church, Tormarton, Glos., George Francis Blacker, M.D., F.R.C.P., third son of Commissioner General Latham Blacker, to Shirley Elvina Bowen, second daughter of Rev. T. J. Bowen, Rector of Tormarton.

**BROWN-NORMANDY**.—On Nov. 12th at Bombay, Capt. Robt. Brown, M.D., R.A.M.C., of Lucknow, eldest son of Dr. Eos-Brown of Strood, Kent, to Pauline Mary Elvina, eldest daughter of Frank Normandy, of Sutton, Surrey.

**KILNER—FRATT**.—On Nov. 11th, at Colombo, John Newport Kilner, M.B. Lond., Adra, Indian Assistant Medical Officer of the Bengal Nagpur Railway, eldest son of Walter John Kilner M.B. M.R.C.P., Ladbroke Grove, to Mildred, only daughter of John Wyatt Fratt, M.R.C.S., L.R.C.P., Otley, late of Wivelscombe, Somerset.

## Deaths.

**PHILLIPS**.—On Nov. 18th, at his residence, 1, Hyde Park Square, London, Charles, Douglas Ferguson Phillips, M.D., LL.D. F.R.C.S., F.R.S.E., aged 74.

## Original Communications.

### CASES ILLUSTRATING THE MODERN SURGERY OF JOINTS.

By J. JACKSON CLARKE, M.B.Lond., F.R.C.S.,  
Surgeon to the North-West London and City Orthopaedic Hospitals.

**CASE I.—Internal Derangement of the Right Knee.**—A vigorous man, æt. 22, first consulted me on March 8th, 1904. His right knee first became troublesome seven years previously, after a sprain received in playing football. He was obliged to leave the field with his knee flexed. Swelling of the knee rapidly ensued. The knee was bandaged, and the patient was advised to walk. Gradual recovery followed. Since that time the trouble has recurred at intervals, an anæsthetic being occasionally required to overcome the fixed flexion at the joint. It is of interest to note that his father has a similar, but less pronounced trouble with one of his knees. As to the past treatment, he had worn a support consisting of lateral steel bars jointed at the knee, and provided with spring patellar trusses, but without any benefit. Shortly before his first visit to me, in landing from a steamer, patient's knee underwent a twist, and again became locked. An anæsthetic was administered, and the limb manipulated, but this time without success, the knee remaining bent, swollen, and painful. Patient was able to walk a little, the knee being kept stiff and slightly bent. On examination, there was a very marked pit, or sulcus, at the inner side of the knee—a characteristic sign of detachment of the internal semilunar fibro-cartilage. (See Fig. 1.) The joint was distended with fluid, which made the sulcus the more striking. I recommended arthrotomy and removal of the detached tissue.

**Operation.**—On March 12th I made a curved incision over the sulcus, and through this I opened the capsule of the joint as far back as the anterior border of the internal lateral ligament. After all bleeding had been stopped the synovial membrane was opened to the same extent as the capsule—it was thickened, its joint surface was granular and stained a brownish colour. Much synovial fluid, also stained brown from effusion of blood, escaped, and more was forced out by pressing on the joint. The displaced tissues were now visible, and they comprised not only the semilunar cartilage, but a fibrous band (part of the capsule) as thick as an index finger, which had been detached with it. This mass lay between the femoral condyles, only its anterior end being visible. This was grasped by Spencer Wells forceps close up to the anterior attachment, and cut through behind the forceps and its free

end grasped, and by drawing on this by a second pair of forceps and flexing the knee, I was able to remove the anterior two-thirds by means of curved scissors. Most of the tissue grasped by the anterior forceps was also removed. The joint now offered no resistance to extension. The remaining fluid was expressed, the synovial membrane and the capsule were closed by separate continuous silk stitches, and the skin by interrupted silkworm-gut; the joint was firmly bandaged, and an anterior malleable splint applied. Repair was uneventful, the temperature remained normal, and the superficial stitches were removed on the eighth day. After this the patient wore a flannel bandage, practising gentle passive movements. A slight impairment of flexion was present, but had disappeared by April 18th, on which date the fluid had all but disappeared from the joint, and the patient was allowed to walk as much as he felt inclined, only being debarred from running and other athletic exercises. On September 1st, all the fluid had disappeared, and the joint and limb were normal in strength and function.

**Remarks.**—This case is an example of the most severe of the various conditions that are grouped together under the heading of "Internal Derangement of the Knee-Joint." The internal meniscus formed only a minor portion of the mass of tissue that had been torn from the capsule. When the joint was opened, I found it impossible to draw the band to the inner side of the condyle, so I contented myself with cutting off as much as I could reach by passing the curved scissors as far as was safe between the condyles. In operating on these cases, as far as my experience goes, there is not much to choose between a curved transverse (Annandale's) incision and a vertical one. As a point in diagnosis, the presence of a marked sulcus is noteworthy—its deepest part was caused by the attachment of the anterior and detached band of tissue. The accident was predisposed to by a family tendency to looseness of the joints.

**CASE II.—Ankylosis of the Right Hip-joint.—Osteotomy of the Femur.**—Percy —, æt. 25, sent to me by Dr. Morley (Portsmouth) in January, 1904. A robust young man presenting fixed flexion (35°) and adduction of the right hip, and when standing marked lordosis. He had to wear a boot raised two inches to compensate for the apparent shortening, and he limped in walking. A skiagraph showed complete obliteration of the joint cavity without dislocation. The history given was that in 1884 patient was sent to the Alexandra Hospital for disease in the right hip. He remained there one year, extension being applied in bed. At the end of this time he was sent to Bournemouth for six months. During

1888-89 two abscesses formed in the hip, and were opened. The subsequent treatment, concluded in 1890, left patient free from pain, but with the limb fixed in its present position. At the patient's request I admitted him to the City Orthopædic Hospital for treatment of the deformity.

**Operation.**—After ascertaining that there was no movement at the joint by exerting strong leverage upon the thigh, I decided to perform a subtrochanteric osteotomy, removing a wedge of bone, with its base directed externally and posteriorly, and then to wire the fragments together. This done and the wound closed except at its lower angle, where a drain was inserted for twenty-four hours, the modified Thomas's hip-splint, with a foot-piece, previously prepared, was applied. The patient had no pain whatever, and repair was rapid, so that on July 1st (four weeks after operation) I was able to allow the patient to stand up to be photographed. (See Fig. 2.) On August 12th, he was allowed to walk without the splint, some stiffness in the knee, where there was some genu valgum from the previous abnormal direction of the limb, being patient's only complaint. Patient left the hospital on September 10th, 1904, walking comfortably with his boot, raised only half an inch, and when seen two months later he was free from most of the limp in his gait that was present before operation.

**Comment.**—Removal of a wedge of bone in this operation enables the fragments to be firmly coapted by a broad surface, and if the wedge does not comprise the whole width of the bone, it does not entail any shortening. Wiring of the fragments secures the patient against pain or delay of repair, owing to movement and shortening from over-riding of the fragments. The Thomas's hip-splint is far more efficient in preventing any flexion at the seat of operation, and far more comfortable and convenient for nursing than any other form of splint that I have used after this operation—subtrochanteric osteotomy or Cant's operation.

**CASE III.**—*Ankylosis of Many Joints following Acute Osteo-Arthritis.*—Isobella —, æt. 30, thin, very anæmic, perspires a great deal; sent to me at the City Orthopædic Hospital; and I sent her to the North-West London Hospital, where she was admitted on September 30th, 1903. Patient a helpless cripple, unable to stand, walk, or feed herself. Three years previously she was taken ill with what was diagnosed as "acute rheumatoid arthritis," which affected most of her joints; the following list indicates—

1. *Temporo-maxillary joints:* stiff, but not completely fixed, and improving.
2. *Spine:* stiffness and pain in the lower cervical and upper dorsal regions; improved under treatment.
3. *Shoulders:* slightly stiff, getting worse; some grating developed later.
4. *Elbows:* complete bony ankylosis, in rectangular position; muscles greatly wasted.
5. *Wrists and fingers:* joints swollen, stiff, painful, and deformed.
6. *Hip-joints:* apparently normal.
7. *Knees:* both flexed to a right angle, some thickening of synovial membrane, tenderness, much pain on passive movement, which is very limited.

8. *Ankles:* both swollen from superficial œdema, and probably also effusion into joints; both feet dropped into equinus position.

In this case I had the advantage of the help of my colleague, Dr. W. Knowsley Girdley, who undertook the supervision of a course of radiant heat baths, from which the patient derived much relief to the pain in the joints. The plan of surgical treatment that I formed was:—(1) by excision of the joint to free the movements of the right elbow; (2) to correct the flexion of the knees and the equinus deformity of the feet, and finally, if the patient desired it, to excise the left elbow. This plan was carried out with gratifying success. The right elbow was excised on October 1st, the ham-strings were divided by open incisions, and the tendines Achillis were elongated on November 17th. Then walking instruments designed by myself were adjusted, and the patient left the hospital on April 16th, 1904, able to walk about unassisted for the first time for over three years. Quite recently she came to me to ask to have the shoulder-joints operated upon. I found that the grating in them had increased, but I decided to wait before excising them, in order to watch whether any improvement occurs under a course of salicylate of soda and tartrate of iron. At the present time the range of active flexion-extension movement in the right elbow is as shown in Figs. 3 and 4. The power of supination and pronation is limited by the stiffness at the wrist. The muscular power in the arm is now good. The knees have become quite stiff in the straight position, but the ankles have regained an almost normal range of movement.

FIG. 1.—The inner aspect of a knee showing a depression below the front of the inner condyle.

FIG. 2.—A modified Thomas's hip-splint used after subtrochanteric osteotomy. (From a photograph.)

**Remarks.**—The case is one of many similar ones that have come to my notice during the last ten years, similar in all respects, save that this was the only one in which bony ankylosis was present.

and the only one in which the knees became rigid after operation. The ages of onset have varied from two (infantile rheumatoid arthritis) to forty-five years. All have begun more or less acutely, and in all many joints have been affected. All have been bedridden from deformity, being unable to walk on pain and sharp flexion at the knees and the equinus position of the feet. After correction of the deformities and the application of walking instruments, all have been enabled to walk, and that in an increasing degree, and

FIG. 3.—A patient after excision of the elbow, showing degree of voluntary flexion.

FIG. 4.—The same patient showing degree of voluntary extension.

with marked progressive amelioration of the joint symptoms and improvement of the general health.

The bone that was found joining the surfaces in both elbow-joints existed only at scattered points, fibrous adhesions being present elsewhere. The patient's temperature was normal throughout the time that she was in hospital.

### Paris Clinical Lectures.

## DIALYTIC TREATMENT OF AFFECTIONS OF THE STOMACH.

By PROFESSOR G. HAYEM.

[SPECIALLY REPORTED BY OUR PARIS CORRESPONDENT.]

"We have always in our service a certain number of patients suffering from gastric ulcer. This morning, I am going to speak to you of one of them whose history appears interesting, and at the same time I will give you some information on a method of treatment to which I have given the term "dialytic."

The man, of Bulgarian origin, æt. 30, is employed in an office. His father died at sixty-five of some malady unknown to us, while his mother still enjoys good health. No trace of nervous affections could be found in his family. About seven years ago the patient, who was at the time an engine-driver, fell from the engine flat on his face, with extended arms. Carried to his house, he complained of pain in his stomach. During ten days all food taken was rejected. The medical attendant treated him for ulcer of the stomach, and put him on hydric treatment for a week, with alimentary enemas, and afterwards allowed a glass of milk every two hours.

At the end of two months the patient was able to resume his work. Soon after, however, the gastric pains radiating to the back rendered the milk diet again necessary, and after some treatment by magnesia, bismuth, bicarbonate of soda, and codeine, the patient decided to enter the hospital.

Since we have had him under our care, he has not vomited either food or blood, but he suffers from his stomach about half an hour after meals. The pain is situated two fingers' breadth above the umbilicus and is increased by pressure. The patient complains of a burning sensation in the epigastrium and is always constipated. With the exception of the stomach, all the other organs are healthy, but the moral condition is deplorable. The patient is in a state of perpetual anxiety; he thinks that his malady is very grave and can support no noise. The analysis of the contents of the stomach showed hydrochloric acid in excess.

The above symptoms point to the existence of gastric ulcer, probably of traumatic origin. We submitted the patient to the usual treatment of round ulcer, which I have frequently had occasion to mention to you; it comprises one of the saline solutions which form part of the medication which I have called the dialytic treatment.

Having made a study of the principal drugs used in gastric affections as above, I have come to the conviction that all agents susceptible of irritating the mucous membrane of the intestine should be proscribed. Clinical experience has proved to me that the troubles of which dyspeptic patients complain are considerably improved by saline solutions, and these are the only remedies I use in the treatment of this group of affections.

I use the term dialytic medication because I believe that these solutions act partly, at least, by their physical qualities. These solutions are abundantly furnished under different forms by the natural mineral waters, but I seldom prescribe them because they are of a complex composition, and the effects on the organism have not been exactly defined, and I contend that just as good effects can be obtained from the artificial saline solutions. Their composition is more simple and presents the additional advantage of being capable of variation *ad infinitum*.

To acquire sufficient experience I reduced to a very small number the saline solutions I employ, and now know their effects, having prescribed them hundreds of times.

I limited myself to the study of four saline drugs: chloride of sodium, sulphate of soda, bicarbonate of soda and phosphate of soda.

Leaving aside for the moment all theoretical explanation, I am going to simply discuss the practical side of the question.

The solutions I studied are five in number, forming two categories—the solutions which act chiefly on the stomach and those which act on the intestine. I have numbered these solutions for the purpose of our lecture. The first category is represented by solutions of unequal composition.

No. 1 is as follows:—

Bicarbonate of soda, dr.  $\frac{1}{2}$ ;  
Sulphate of soda, dr. 1;  
Chloride of sodium, grs. 20;  
Water, one quart.

This solution can be employed in cases of gastritis with hyperpepsia; it is Carlsbad water simplified, and is used as prescribed at that watering-place.

In the morning, fasting, the patient takes ten ounces in repeated doses (a third part every twenty minutes) warmed to blood heat. This dose is increased by an ounce and a half each day until a pint has been reached. The cure should not exceed twenty-five days. The counter-indication to this solution is dilatation from want of tone of the stomach. The stomach which empties itself with difficulty should be otherwise treated.

Disease of the heart with tendency to oedema constitutes another counter-indication as well as cancer. I warn you against employing this solution with patients suffering from cancer. How often do we see each year cancer patients going to take a cure at Carlsbad and returning completely depressed?

The second solution is as follows:—

Chloride of sodium, dr. 1;  
Sulphate of soda, dr.  $\frac{1}{2}$ ;  
Water, one quart.

Employed generally cold at the dose of nine ounces taken at once, an hour before breakfast. The duration of the cure is six weeks.

The indications of this solution are very numerous. It can be used in slight hypopepsia with weak secretion; it answers to immediate indications by which we begin in the majority of cases.

The third solution:—

Chloride of sodium, dr. 1;  
Phosphate of soda, dr.  $\frac{1}{2}$ ;  
Water, one quart.

Is to be prescribed in cases of intense hypopepsia or apepsia, and is especially indicated in debilitated subjects.

Solution No. 4:—

Chloride of sodium dr.  $\frac{1}{2}$ ;  
Sulphate of soda, dr. 1;  
Water, one quart.

Is to be given warm in cases of large liver and atony of the intestine.

Solution No. 5:—

Chloride of sodium, dr.  $1\frac{1}{2}$ ;  
Sulphate of soda, dr.  $2\frac{1}{2}$ ;  
Water, one quart.

About twice the strength of No. 4, this solution is given in similar cases, half a glass fasting, and if well borne another half-glass a quarter of an hour after.

You have observed that all our solutions contain chloride of sodium, and before concluding, I wish to give you some information concerning the rôle played by salt in the treatment of gastric affections. Solutions containing chloride of sodium take a special place on account of the chloride constitution of the blood and gastric juice. Other things being equal, the more chloride of sodium furnished to the organism, the richer is the gastric secretion in chloride products. Thus the solution which I employ in the hypopeptic conditions contains a relatively large proportion of chloride of sodium (5-1000).

On the other hand, the chlorides should be diminished in hypopepsia, and this has been done empirically for a long time by prescribing the milk diet, especially in cases of ulcer. But the effects produced by this hypochloridation depend, in part at least, on the state of the mucous membrane of the stomach. The results are variable according to the nature of the case, whether it be one of mixed or parenchymatous gastritis. Where there is hyperpepsia in either of these affections, the milk diet tends at first to diminish the chlorides, but to obtain a permanent effect, it should be continued several months.

Widal and Javal having recently drawn attention to alimentation without salt in a case of Bright's disease, some doctors proposed the régime without salt for hyperpepsia, yet the same result could be obtained by giving large doses of bismuth, and a cure with the artificial solutions of Carlsbad, which cause the digestive troubles and dilatation to disappear if present.

## CONSTIPATION.

By TOM ROBINSON, M.D. St. And.

ANY medical man who is brought into contact with the public must be impressed with the number of individuals who are in the habit of taking aperient medicines. The habit is not confined to any age, class, or sex, but it certainly predominates among women. Some will swallow gallons of the mineral waters during the year; others will fly to the commoner aperients, such as Epsom salts or compound liquorice powder; many even drop into the pernicious habit of taking as frequently as every night a pill or compressed tabloid containing aloes. The habit is continued until the muscles of the bowels lean so long upon these crutches that they become weak, and the victims suffer from windy colic, internal rumblings, and often considerable irritation of the mucous membrane of the intestinal canal. The feebleness of the bowels may be so marked as to lead to complete stoppage.

In these few remarks on constipation it is my

intention to eliminate all those cases which are caused by any growth or other mechanical pressure. And I shall not either show cause why it is often of enormous advantage to administer what our predecessors so well called a "brisk purge."

Rightly or wrongly the ordinary citizen has a fixed and unalterable idea that for his well-being it is of absolute necessity that once every twenty-four hours the bowels must act. Our problem is how we are to produce this peace of mind without giving aperients. Our mode of procedure must be based upon the axiom that all effects have a cause. The cause of sluggish bowels are threefold:—

- (a) Insufficient and unwise diet.
- (b) The habitual taking of purgatives.
- (c) Deficiency in the muscular energy of the bowel.

In considering insufficient and unwise diet, we must remember that fæces only represent the waste products of the body; hence it follows that the diet must embrace a sufficient quantity of food which cannot be digested, and which, passing along the bowel way, stimulates that bowel to contraction, and by so doing urges on the fæcal wave. Brown bread and figs stand out as common examples. These are often not sufficient, and we must find other means.

Some time ago I was in the country and was watching some bullocks during the winter months, when the farmer's usually house them and give them linseed cake, and one could not help being impressed with the easy way in which these bullocks defæcated. This easy action of the bowels also takes place in grazing beasts. The thought struck me, why not give my costive patients linseed? one cannot give them grass. On returning to my work, I soon had an opportunity for putting my idea into practice, and ordered my first patient who was the victim of constipation to take one teaspoonful of flax seed floating in a goblet of cold water every morning before breakfast, and to repeat the remedy again in the forenoon until the bowels resumed a healthy function, impressing upon the patient the fact that time must elapse before the desired condition ensued. In three days the desired condition did ensue, and now, so far as I know, the sufferer is happy every morning owing to the fact that at a given hour fæcal relief is obtained.

There is one after-factor in the treatment, which is to insist on the patient drinking at least three pints of liquid every twenty-four hours. We must at the same time absolutely forbid the taking of any aperients. It is often asserted that some of our mineral waters, the pills and tabloids of commerce, do not cause constipation. This must be a fundamental error. Constipation follows the habitual use of any aperient medicine. It is a natural law, because every purgative acts by virtue of its power to increase the fluidity and quantity of the fæcal relief—*ergo*, after taking aperients these must be diminished.

Time and a healthy, regular, outdoor life will bring about the last condition, which, of course, is the final one. Give the thirty feet of intestinal tubing plenty of work to do and its muscular coat will become lusty.

## SOME ASPECTS OF METABOLISM—CHIEFLY CLINICAL. (a)

By WILLIAM CALWELL, M.A., M.D.,

President of the Ulster Medical Society; Physician to the Belfast Royal Victoria Hospital,

PART I.

GENTLEMEN,—An inevitable difficulty presents itself of the selection of a subject on which to address you. The embarrassment of riches in matters to be handled is great. There are the University question, medical education, medical politics, and medical ethics, the hospital system of the day, when philanthropists look askance upon the iniquity of demoralising children in the street by giving them a penny, but with complacency devote thousands in supplying to their parents what they are in many cases well able to procure for themselves, or would, had they not squandered their wages in miserable and unrestrained drunkenness. No one will deny that care should be taken of the flotsam and jetsam of our urban population, and a helping hand given to the industrious but unfortunate, whether from accident or disease, in life's struggle; but we cannot hide from ourselves that indiscriminate charity emasculates the energy, self-respect, and independence of the recipient, and tends to breed a rank and overgrown vegetation sadly needing the impartial weeding of Nature.

The relations between the various professions offer a rich mine to furnish material for introductory addresses. Since the Beck case, the law will probably be somewhat less bumptious, and will curb its mild jokes on doctors differing and mistaken diagnoses. However, we of medicine live in glass houses; and our decisions are occasionally of the same trustworthiness as that of the Beck case, even those that are delivered in our final courts of appeal. The value of much of our more abstruse and specialised scientific work has lately been debated. As an educational procedure it is invaluable; as a means of examination of a patient it is also of the greatest service; but microscopic sections and bacterial growths, blood films and cryoscopy are all liable to mistakes and fallacies, just as auscultation and percussion are, and the interpretation of results is all based upon experience. The laboratory is not a final court of appeal, but is simply a witness giving evidence, and that evidence may be most valuable, accurate and decisive, or useless, faulty, and of no moment. The responsibility rests with the practitioner; it cannot be delegated to others; it may be shared, or refused altogether; but it is the inalienable duty of the medical man in charge of a case to collect all the evidence he can, and come to a conclusion himself; and it is a pernicious doctrine to preach that a man who has never seen the patient should diagnose the disease.

Leaving, however, these subjects, as they furnish matter of daily debate and of correspondence in our papers, and as I have little or no especial experience or taste in them, I turn to a more personal choice. In looking over my own small contribution, which I had the honour of making to this or other medical gatherings, or to journals, I find there are two classes of disease which engaged attention somewhat more, perhaps, than others. For ten years I was medical attendant at the Throne Consumptive Hospital, and I believe I was the first in Ireland to advocate and to adopt the present method of treatment. I visited some of the German sanatoria and described my subsequent experiences on more than one occasion. But since this revolution of hyper-ventilation and hyper-alimentation but little new in principle has been developed. It would be worse than useless to reiterate the old discussions; the trial has taken place, the advocates have aired their eloquence, the judge has summed up, and now the jury, composed of thousands

(a) Opening Address delivered before the Ulster Medical Society, Session 1904-05.

of consumptives scattered over the realms of all civilised kingdoms, are debating in their own chests and tissues whether the hygienic treatment is a beneficent angel or a quack, a base fraud and deception. The deliberations of the jury are not yet approaching an end, and for the next ten or fifteen years they should be left in peace. Some new series of statistics or some paper embodying the results of experience are added from time to time. No final verdict can be given yet. My own opinion is unchanged. One may not approve of all the details, but the method is an immense advance to a higher, more logical, brighter and happier life, not only among the consumptive, but in every path of life.

In 1899, two years before the publication of Mayb Robson's "Diseases of the Stomach and their Surgical Treatment," I read a short paper at Portsmouth on organic adhesions of the stomach as a cause for some forms of dyspepsia, and recommended mechanical interference. Since then, experience has grown and earlier opinions have been modified. But it is now a recognised principle that cases of chronic dyspepsia showing signs of ulceration, past or present, of cicatrization and adhesions, should not be allowed to starve into a painful, miserable, and too-long-delayed death, but should take their courage in their hands and risk the great issue for the chance of formerly undreamt-of recovery. Here surgery has achieved one of its most signal victories. It is true that the description of the old English surgeon is not quite banished; some of the operations are still "terrible in the doing and melancholy in the event"; but when we consider the hopelessness of the case, and the large portion of success that attends interference, we must congratulate ourselves on the merits of the school of surgery in our midst, not merely in abdominal work, but in the general principles, *technique*, of our surgery as a whole. As part of this second point on which I have laid stress, both before my fellow medical men and in teaching at the bedside, I may mention the constant connection of chlorosis and gastric ulcer, so that it has become a fad with me—as all somewhat novel and strange convictions are politely termed by one's friends—that the so-called tea-dyspepsia of anæmic girls are really small, rapidly forming, and happily often rapidly healing gastric ulcers; and that such ulcers are a local manifestation of a constitutional affection. They are often overlooked, but at times prove their importance in an unmistakable manner and usurp the throne of the premier disease. I have, however, no new facts to put before you on either of these issues. Besides, like the consumptive problem, the principle has been affirmed; we require the experience of years to mould it, so that the finally developed procedure may pass into the accepted canons of our art.

I have been endeavouring to classify for my own edification diseases of the stomach other than cancer and ulcer, but have found the connections between pure gastric and gastro-intestinal-hepatic affection so close that it is nearly impossible to draw a line of demarcation. I thought, therefore, of abandoning a frontal attack, and approaching the stomach from the other or hepatic side before dealing further with gastric or intestinal derangements.

During both studies of phthisis and gastric troubles, if I may so dignify these very incomplete observations, the groundwork or constitution of a patient on which we, as professional artists, had to work was forced upon my attention not once or twice, but at every turn and move. However, of a man's inherited qualities the study is entrancing, but, as regards practical therapeutics, somewhat wanting in hope. We cannot treat a patient's grandfather, although the Chinese may ennoble him, and nothing less than the unremitting treatment, preventive and curative, of four grandparents and two parents could remove the vice of blood and tissue from some patients. The effect by his environment on the other hand, is all important, and the effect of environment on the problems of metabolism constantly recur in dealing with disease in the province of the physician. It is one personally I have

been drawn closely to latterly, and I propose to make a somewhat rapid survey of the subject from a clinical aspect.

Evolution does not give much help. Plants are able to form their protoplasm from the constituents of the atmosphere, or the inorganic matter of the earth. By the sun's rays and their own inherent vitality they build organic matter of high potential energy from CO<sub>2</sub>, ammonia, nitrates, and mineral salts. The earliest appear to be sugar and starch, and by synthesis fats and proteids follow. One need have little doubt that could the evolutionary chemist of biology fathom the secrets of comparative physiology he would be able to trace the various stages of growth in lines radiating from the most elementary organic molecule in various directions of vegetable and animal life; and in that radius, at the end of which is man, ending in some molecule more complicated than that of the proteid of hæmoglobin.

In mental disease, help is obtained by a study of comparative mental physiology, in which we may include not only the study of animal mind of various stages of evolution, but also the growth of the child's mind with various stages of development. I have no doubt also that most interesting facts, important in the light they would throw on the etiology and treatment, will be discovered in metabolism. At present, however, such few details as I have been able to glean are not of sufficient importance to warrant me in detaining you longer than simply throwing out the suggestion. Reversion to ancestral types may be present, but so far its study is not of practical importance. The same may be said of child development.

In order to refresh our minds on some points of elementary physiology, I shall very briefly run over the accepted dicta of the changes which food undergoes after the action of the digestive juices has been exercised upon them.

Of proteid matter, the peptone formed in the alimentary canal is converted by the agency of the columnar epithelial cells of the mucous membrane of the intestine, back again to some more ordinary form of serum and globulin albumen; for no trace of peptone is found in the portal vein, although serum and globulin albumen is found in excess during a proteid meal. Injection of small quantities of peptone into the portal vein gives rise to peptonuria.

In the liver, no doubt, this albumen undergoes some further change, possibly some of it is converted into glycogen, but physiologists are rather in a fog in this region, and the intricacy of the subject is such that the most careful investigations and experiments fail to allow more than probable surmises. It then circulates through the body in solution in the serum; some small portion is assimilated by the fixed and floating cells and tissues, but the great mass of absorbed albumen remains in solution, and seems to act as a source of energy without being taken up into the tissues and organised. The exact subsequent changes form a subject of conjecture, or perhaps of logical inference, and are as mysterious as the movements of the Japanese army in Manchuria. It were too great a prerogative even for the presidential chair to inflict upon you a tithe of the names assigned to analogous changes in the test tube; finally, however, we meet with urea at the end of these long subcuticular wanderings, most probably formed in the liver and excreted by the kidneys.

Of the carbohydrates, the starches or poly-saccharides, and the cane-sugars or di-saccharides, are reduced by the saliva and pancreatic secretions to a monosaccharide such as dextrose. In the columnar epithelial cells of the villi, some change comes over this dextrose, as the carbohydrate found in the portal vein has a lower cupric oxide reducing power than dextrose. In the liver a return to the poly-saccharides is found in glycogen. What happens next is a matter of dispute. Pavy says sugar does not and should not reach the general circulation; others say that the glycogen is slowly given off as some form of sugar, which is used up in the fixed cells and in the lymph circulation, and disappears as water and carbonic di-oxide.

Fats are split in the intestine into fatty acids and glycerine. The former are reconverted into neutral fats by the columnar epithelial cells of the intestinal mucosa; and these fats are oxidised in the circulation into  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

The principles of the complicated chemical changes are not difficult to understand. On the one hand, by the agency of ferment the larger molecules of both proteid and carbohydrate are split up into smaller; this process is accompanied by hydration; there is a conversion of a high potential energy into a lower; but the molecule can now be absorbed. The process is exemplified in albumen and peptone, starch and dextrose, perhaps glycogen and dextrose, where the ferment is an internal secretion of the liver. On the other hand, by the agency of living protoplasmic matter, dehydration takes place, there is a combination of molecules, a formation of a molecule of higher potential energy, a synthesis of living matter, an absorption into the living protoplasm of a cell. As examples of this synthesis, we may adduce the formation of fat from a carbohydrate, or of the complex conjugated proteid as nuclein from simple proteid, fat, and carbohydrate. In the exercise of functions these complex compounds are broken, and this disintegration is mostly a question of oxidation. It is impossible to assign many of these substances to their exact place in the circuit of metabolism. Pavy assigns a great importance to the protoplasmic agency by the intestinal villi in the conversion of a dextrose into a high carbohydrate, so that no sugar should reach the blood circulation. In these cells he says there is a transformation of the sugar into fat, a synthesis into proteid and a transmutation into glycogen. We can easily understand how these delicate and complicated processes may be thrown out of gear.

(To be concluded.)

### Clinical Records.

#### A CASE OF OVARIAN DISEASE ASSOCIATED WITH UTERINE FIBROIDS. (a)

By BEDFORD FENWICK, M.D.,

Physician to the Hospital for Women, Soho Square.

THE specimen which I now show was taken from a patient, æt. 44, and unmarried, who was sent to me by Dr. Richmond, of Wimbledon. Ten years ago, she was told by a well-known obstetric physician that she had a fibroid tumour, but it would disappear at the change of life. It almost seems too much to hope that this antediluvian superstition will ever be decently buried, because one is constantly meeting with it in the case of patients with uterine fibroids who have passed through years of needless suffering and danger whilst waiting for a menopausal millennium. For the past six months, the patient has suffered from increasing pain in the abdomen, especially on the right side, and from increasing loss of flesh and strength. I performed abdominal section on October 24th, and had some difficulty in lifting up the mass as it was completely moulded into the shape of the pelvis. It was also exercising considerable pressure on, and causing some displacement of, the left side of the bladder. I performed hysterectomy in the usual manner, and as both ovaries were grossly diseased, removed them with the tumour. I then observed that the left ureter was greatly dilated, being about three times its normal calibre, evidently due to the effect of compression on the base of the bladder by the tumour. I had predicted this condition before operation, and had the urine measured carefully for a week previously, the average amount being only 35 oz. a day. Directly after the tumour was removed, the bladder rapidly filled, proving that there must have been a considerable collection of urine in the ureter and calyx of the left kidney, and after the operation the average amount of urine per diem rose at once to 55 oz. I feel confident that sufficient stress is not laid upon the danger to the

kidney caused by pressure on the ureter by fibroids of the uterus. Indeed, I regard this as one of the most serious and insidious complications to which these patients are liable. I desire to call special attention to the gross disease in both the ovaries attached to the tumour. The left ovary was converted into a blood cyst containing 8 oz. or 9 oz. of black blood. The right ovary contained about 4 oz. of congealed blood, about half its cavity being filled with a dense nodular growth, which has thinned the capsule at one part to a thickness of only one-tenth of an inch. The growth cut like scirrhous, and I am indebted to Dr. Aarons for the sections which are shown to-night, and which prove that the growth is a fibro-adenoma. In the next place I wish to call attention to the remarkable size of the ovarian arteries, which are four or five times their normal calibre. Dr. Aarons has kindly also made sections of these, and it will be observed that the middle coat of the artery is greatly hypertrophied. It will be within the memory of the Society that a distinguished Fellow, at a meeting some two years ago, showed a number of microscopic sections proving that the uterine arteries are greatly thickened in cases of fibroid disease of the uterus, and that he expressed his belief that this condition was the cause of the fibroid change. I then, and have since, ventured to point out that there is reason to believe that the increased hypertrophy of the uterine arteries is the consequence and not the cause of the fibroid change, and precisely resembles the hypertrophy of the muscle of the heart or of other arteries in the body where the circulation is called upon to overcome an increased difficulty or obstruction to the blood stream. And this case, and others which I have shown, in which the similar hypertrophy of the ovarian arteries occurs, goes further to prove my argument. But there is a practical point to which I have also drawn attention, and which this case strongly supports: that whenever we have fibroid thickening to any marked degree at the fundus of the uterus—that is to say, where the ovarian arteries enter the uterine tissue—then, and then only, will there be much obstruction to the flow through the ovarian vessels; then, and then only, do we find hypertrophy of the muscular coat of the ovarian artery; and then, and I am inclined to believe then only, do we find ovarian disease associated with the presence of the uterine growth. I would venture to emphasise these facts, because they have assisted me much in practice in this way: that when I find the fundus fairly free from fibroid growths I always leave the ovaries with an easy conscience, but when there are fibroids on one or both sides of the fundus, and considerable enlargement of the ovarian artery, I have always found sufficient disease in one or both ovaries to make it evidently advisable that they should be removed.

### British Health Resorts.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]  
XVII.—PENZANCE.

CORNWALL has been described as the foot of England, the Lizard the heel, and the Land's End the toe. Towards the western portion of the arch lies Mount's Bay, and on it Penzance, which for long has won distinction as a most desirable winter resort for invalids, and a charming holiday centre in spring and during early summer. It is the metropolis of the western part of the Delectable Duchy, and forms an admirable residence for cases which require to live an open-air life during winter days, and yet are reluctant to leave the shores of the homeland.

The town is situated on the side of a declivity on the north-west shore of Mount's Bay. It is sheltered and yet lies open to the exposure of the bay, and while affording the comforts of a land residence, provides the advantages of a marine climate. Penzance records show that it enjoys the highest mean annual temperature of any British station on the Royal Meteorological Society's list. There is almost complete absence of extremes of temperature. The degree of humidity is

(a) Read at a meeting of the British Gynecological Society, November 16th, 1904.

comparatively low, and much sunshine prevails. During the six months comprised in the first and last quarters of the year it holds the record for warmth in the British Isles.

Snow is seldom seen, and severe frosts are rare. Penzance has been well characterised as "A Paradise for invalids." (a) The climatological report of Mr. C. H. Benn, the Borough Meteorologist, for 1903 (b) affords the following data:—"The mean temperature for the year was 52.41° F. The mean temperature for the winter months was 48.31° F. The winter mean range was 7.37°. The total sunshine is recorded as being 1,752 hours 25 minutes, a daily average of 4 hours 48 minutes and 2 seconds. The mean humidity is returned as 79 per cent., and the rainfall last year, which, of course, was unusually heavy, was 51.11 inches.

Penzance may well be selected as a good winter home for invalid and delicate cases who need outdoor life, a marine climate, and are interested in artistic influences. Newlyn, which is now practically a suburb of Penzance, has given its name to a renowned school of artists.

Patients, the subjects of chronic respiratory affections, find much that is congenial and attractive in this western seaside station. Many tuberculous cases here weather the winter well. Renal cases are also said to gain benefit. There is difference of opinion as to the value of the place in the management of asthma. Some cases of anæmia, and not a few cutaneous disorders, reap no benefit. For the convalescent and those who are to be considered vigorous invalids, the neighbourhood of Penzance can offer much that is peculiarly attractive.

The Isles of Scilly, which lie off the Cornish coast in the Atlantic, if it were not for the difficulty of reaching them, might form a veritable marine sanatorium. (c) Penzance is 321 miles distant from Paddington, but the enterprise of the Great Western Railway has rendered the journey easy, and the invalid can now travel in comparative luxury in seven hours.

## Transactions of Societies.

### BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD NOVEMBER 10TH, 1904.

PROFESSOR JOHN W. TAYLOR, M.D., F.R.C.S., President, in the Chair.

#### EXHIBITS.

DR. MACNAUGHTON-JONES read the pathological reports on two cases of embedded adnexal tumours, which had been completely hidden by perimetritic exudation, and, later, exhibited with the epididymal sections of the tube illustrative of desquamative salpingitis. He raised the question of the necessity of hysterectomy if the uterus were not materially affected.

DR. R. H. HODGSON asked whether he correctly understood Dr. Macnaughton-Jones to attribute all the pain in salpingo-oöphoritis to peritonitis. Surely pain in an ovary or tube did not necessarily imply the presence of any peritonitis.

DR. HEYWOOD SMITH said that in deciding as to the removal of the uterus in ovarian disease one had to consider the age of the patient and whether she was, or was not, married. In his experience, the removal of the ovaries alone did not interfere with sexual appetite, which, when the uterus was also taken away, was very much deteriorated.

The PRESIDENT concurred with Dr. Macnaughton-Jones that it was, as a rule, an advantage to retain a uterus that was comparatively healthy; at the same time, even in abdominal operations, he found

himself more and more inclined to begin by curetting the uterus if he had any reason to think there was any endometritis.

DR. MACNAUGHTON-JONES, in reply, said that he had expressed no opinion in regard to the pain; Dr. Cuthbert Lockyer's report did, however, refer to the considerable influence which contractions of the hypertrophied muscular tissue of the so-called uterine platysma had on the clinical aspect of such cases. He had been recently informed by a patient from whom he had removed both ovaries, and on a subsequent occasion the uterus also, that her sexual appetite had not been in the least affected.

#### DR. BEDFORD FENWICK read notes on a case of OVARIAN DISEASE ASSOCIATED WITH UTERINE FIBROIDS,

which will be found under the heading "Clinical Records," upon page 541, and exhibited specimens.

The PRESIDENT said that he had occasionally, but only occasionally, found large blood cysts of the ovary in association with myoma of the uterus, in one instance as large as an ordinary water bottle, and in another as large in diameter as an adult's arm, and containing a quantity of black blood. In the cases he could call to mind the tubes had been quite free, and it did not seem that such cysts could be directly connected with menstruation, or with regurgitation of blood from the tubes. The pathogenesis of these cysts was very obscure, and he would be glad to hear if Dr. Bedford Fenwick had formulated, or knew of, any theory about the matter.

MR. CHRISTOPHER MARTIN said that, in his opinion, the most urgent of all indications for operative interference in fibroids was pelvic pressure, especially pressure upon the bladder and ureters. But pressure on the ureter in many cases added enormously to the risk of the operation, especially when the tumour was very adherent in the pelvis. In removing such a tumour not long ago (a fibroid embedded in the pelvis) he found one and a half inch of the ureter lying in a groove at the side of the mass removed. He performed nephrectomy on the corresponding side, but the patient died the next day from shock. In regard to Dr. Fenwick's theory of the causation of ovarian disease by pressure of a fibroid on the ovarian artery, that would not, he thought, justify the removal of an ovary apparently healthy; it was reasonable to suppose that when the tumour, and the pressure, were removed the circulation in the ovary would become normal again. Except for gross disease, it was better not to remove an ovary.

DR. FENWICK, in reply to the President's question, said that he had looked up the text-books on this very point some two or three years ago, and had been unable to find any explanation given, and in several no mention was made of the ovarian changes in fibroid disease of the uterus. The theory he had ventured to advance at this Society was, of course, only a theory, and nothing more; but it seemed to him to be not only plausible, but sufficient to explain the pathology. Increased power in the ovarian artery, combined with increased difficulty in the ovarian circulation at the uterine fundus, must inevitably mean a constant hyper-congestion of the intervening tissues, that is to say, in the ovary itself; and the effect of such congestion must be not only the production of inflammatory changes, but, in the case of such an organ as the ovary, a greater likelihood of cystic degeneration; and, given the formation of a cyst, the greater probability of rupture of a vessel, or of exudation of serum into the cavity, of rapid increase in the cystic area; or, in other words, of the production of the very condition shown in the specimen he had just brought before the Society, and he would point out that even if there was no rupture of a blood-vessel, the vascular changes would still explain the production of other forms of degeneration which are known to be associated with ovarian disease.

DR. HEYWOOD SMITH showed a uterus containing numerous fibroid tumours, one in process of sloughing; the right ovary was converted into a large blood

cyst, the left, though slightly enlarged, had not been removed, as the patient was young. An interesting point in the case was that the patient's temperature had been persistently subnormal, and that, in spite of the sloughing tumour, there had been no symptom to suggest suppuration.

Dr. HEYWOOD SMITH also showed, for Dr. Alexander Duke, a device for the removal of wet wool from a Playfair's probe, often in some hands a difficult proceeding. It consists of a little metal frame with a slot wider at one end. The probe is passed through the wide end, and on being pushed towards the narrower part, the wool is then easily slipped off.

Dr. BEDFORD FENWICK pointed out that in Dr. Heywood Smith's specimen the ovarian artery was greatly hypertrophied, being at the point where it was divided nearly double the normal size.

The PRESIDENT said that in connection with the interesting specimen shown by Dr. Macnaughton-Jones at their last meeting they had to discuss the condition known as hæmorrhagic endometritis.

Dr. MACNAUGHTON-JONES said he had brought the specimen again, but had little to add to his remarks at the last meeting. Cases of glandular endometritis attended with persistently recurrent hæmorrhage might pass into what was practically a form of pernicious anæmia, in which the condition of the woman was almost as bad as if she were suffering from malignant disease, and if bleeding recurred there was no hope but removal of the uterus.

Mr. CHARLES RYALL said that some years ago he had shown to the Society two specimens removed by hysterectomy, and his treatment met with a good deal of adverse criticism at the time, but in the condition described by Dr. Macnaughton-Jones, extensive hyperplasia of the endometrium with increase of the muscular and fibrous tissue, and general thickening of the uterine wall and some endarteritis, the curette, though repeatedly resorted to, seldom gave relief, indeed, generally made things worse; and for obstinately recurring hæmorrhage in such cases, removal of the uterus was the best treatment.

Dr. J. J. MACAN reminded the Fellows that the term "hæmorrhagic endometritis" was originally applied by Slaviansky some fifteen years ago to cases of profuse uterine hæmorrhage associated with inflammation, affecting chiefly the glandular elements of the endometrium, during an epidemic of cholera. The term, as Veit mentions, has been also applied to uterine hæmorrhages occurring during the course of the exanthemata. A report of one such case will be found in the number of the Society's journal now in the press.

Dr. MACNAUGHTON-JONES, in reply, said that he could understand the term hæmorrhagic endometritis being used in connection with the exanthemata, for during eleven years' work in a large fever hospital he had seen many cases of hæmorrhage from the uterus, but he attributed that hæmorrhage to a change in the blood rather than to any affection of the uterus. The condition he had brought under the notice of the Society was generally the result of long pathological change, and the question was, not so much the cause of the hæmorrhage, as the passing of some of these cases of glandular hypertrophy and desquamation into a state approaching malign adenoma.

Discussion on Mr. Christopher Martin's paper on the TREATMENT OF INTRACTABLE PROLAPSE BY EXTIRPATION OF THE UTERUS AND VAGINA.

(Vide ante MEDICAL PRESS AND CIRCULAR, October 26th, 1904. Page 429.)

Dr. J. A. MANSSELL MOULLIN said Mr. Martin had brought before the Society a new operation for the treatment of this distressing condition. Mr. Martin recognised the futility, or, at any rate, the temporary nature of the benefit to be derived from the many operations hitherto devised for the correction of prolapse. The operation now proposed did not rest on the cutting away and puncturing of tegumentary structures, but on a more solid and scientific basis, namely the union and reconstruction of the fascia

to form a pelvic floor resembling that of the male pelvis. It was well known that to repair a hernia occurring in the cicatrix of an abdominal incision it was essential to expose and unite the cut edge of the transversalis fascia. If this was done effectually, a good result was certain, otherwise the operation was in vain. Mr. Martin tells us that the pelvic fascia, which splits to enclose the upper portion of the vagina, does not itself become prolapsed, but that the uterus and vagina are prolapsed and stretched away from it. When these latter are removed, the cut margin of the fascia can be readily distinguished and united with sutures to the opposite side, thus obliterating the opening through which the vagina passes, and forming a continuous pelvic floor. Mr. Martin does not conceal the fact that the operation is a formidable one, and attended by many risks. An improved technique may possibly enable us to add it to our remedies for use in severe cases.

Dr. R. H. HODGSON, after complimenting Mr. Martin on the frank way in which he had given the details of his cases, said that it was noticeable that the fever and suppuration which in three cases did not occur till after ten days, in the fourth appeared on the second day after the operation. It seemed, therefore, probable that this fourth case was one of infection at the time of operation; the others, due to some change in blood-clots formed in the wound. The great tendency of blood-clots in the pelvis to undergo decomposition might, he suggested, be due to their proximity to the rectum, and to the difference between the coverings of the intestine outside and within the abdominal cavity. He had himself suggested some years ago that prolapse might be remedied, or prevented, by amputating the uterus at the internal os, drawing down the free edges of the broad ligaments through the cervix, and so making all the parts taut. This would save the vagina, which it was desirable to do, even in a woman getting on in years.

Dr. BEDFORD FENWICK said that he considered the Society owed a debt of gratitude to Mr. Martin for the excellent paper he had brought before them, and personally he much admired the skill and courage displayed in the operation Mr. Martin had described, because, to anyone who was constantly accustomed to operate on the abdomen or vagina, it needed no words to explain the difficulties of the operation in question. There were one or two matters which had particularly struck him in Mr. Martin's description. In the first place, he could not understand the special advantage of removing the mucous membrane from the anterior wall of the vagina, but as Mr. Martin did it, it seemed to him to explain all the suppuration to which Mr. Martin referred; for example, he apparently left an entirely raw surface in the canal, which was closed by granulation, which involved the formation of pus. If the lower part of the canal closed first, as it most probably would do, then the pus must collect at the top of the canal, and of course the septic conditions to which Mr. Martin referred naturally followed. Mr. Martin, indeed, seemed to have realised this, because he in each case passed a pair of forceps along the canal, liberated the accumulated pus, and the patient at once recovered. If he (Dr. Fenwick) were going to perform this operation, he would certainly feel inclined to modify it, therefore, to the extent of leaving the mucous membrane on the anterior wall untouched, and thus saving what everyone would know to be the most difficult part of the operation. Then by stitching its edges together one could reduce the canal to the diameter of an ordinary pencil, and in the great majority of severe cases he could not but think that colporrhaphy to this extent would be sufficient to entirely cure the patient. Moreover, it would leave no suppurating surface, it would not interfere with the relations of the uterus and ovaries, but it would to all intents and purposes close the canal into and through which prolapse of the rectum or bladder could occur. Then, again, in Mr. Martin's operation he could not but think that there must be a great practical difficulty sometimes in finding the

pelvic fascia, and when it had been found in drawing it together sufficiently to close the base of the pelvis, which, as he understood the procedure, was the scientific principle on which Mr. Martin's operation was founded, and which, as a principle, both anatomical and pathological, he cordially accepted. Nature had created a wide separation between the fascia, and in his experience it was in some cases not easily found. He, therefore, was inclined to believe that cases might occur in which the edge of the fascia could not be defined, and others in which it would not be possible, by any permissible traction, to draw the edges of the fascia into a sufficiently accurate position to obtain firm union.

Dr. MACNAUGHTON-JONES commented on the fact that only on the rarest occasions was such an operation called for, as acknowledged by Mr. Martin himself. He (Dr. Macnaughton-Jones) had on three occasions removed the uterus and then performed free colporrhaphy. In these cases the bladder and bowel were down in the proident sac. They were all permanently relieved. It was rarely indeed where even this step was necessary. A Schroeder's operation, consisting of colporrhaphy and high amputation of the cervix, with a deep perineorrhaphy, was sufficient in the majority of instances, combined, if need be, with a ventrofixation, or better still, an Alexander-Adams operation. So far back as 1889 Professor A. Martin (now of Greifswald) had performed complete extirpation of the vagina and uterus for both cancer and proidentia. The operation differed in the two instances. In 2,000 cases of proidentia, up to the end of 1903, Professor Martin had performed total extirpation nineteen times. He removed the adnexa also. In commencing all such operations a good deal of bleeding might be avoided by early ligation of the vaginal branches on the uterine trunks. The rarity of the operation did not detract from the boldness or ingenuity of the procedure.

Dr. JERVOIS AARONS said that he was much struck with the ingenuity of Mr. Martin's operation. He had, since the paper was read, seen a case of prolapse which recurred after hysteropexy, perineorrhaphy and anterior and posterior colporrhaphy, and for such a case, especially in a woman past the menopause, the method promised relief otherwise unattainable.

The PRESIDENT said: I have watched with very great interest the work of my colleague, Mr. Christopher Martin, on the extirpation of the uterus and vagina for the treatment of severe prolapse, and can, from my own observation, confirm a good deal of what he has told us. But while I can and do most heartily admire the use of thought and skill which are united in the performance of this long and difficult operation (for there is one part at least in its performance when, if I remember rightly, as the uterus is turned downwards and backwards, all ordinary relations are more or less reversed, and every attention and care is necessary to understand as well as to perform the work), I am not fully satisfied after all is completed that the best has been done for the patient. The loss of the vagina is a serious loss, and what Mr. Martin regards, and rightly regards, as the essential part of the operation—the rebuilding up of the stretched pelvic fascia—can be obtained in another way, I think, without the loss of the whole vagina. If, after starting to repair a perineum by Mr. Tait's method of flap-splitting, the upper flap of the posterior vaginal wall be grasped by the left thumb and forefinger and the scissors dissection be carried up higher and higher between the rectum and vagina, a plane is finally reached where there is only the firmest union between the vagina and rectum, and the finger can bluntly separate the two right up to the cervix if necessary. Now, if this be done, the separation being not only carried high enough but extended (by dissection) freely on both sides, and the long, triangular flap of vaginal membrane thus produced be fully excised, you find a condition exactly similar to that produced by Mr. Martin in its free exposure of the pelvic or recto-vesical fascia. Some of this has been already removed by the removal of the vaginal

floor above it, and you can see the edge of the fascia as a distinct structure on each side, a divided membrane, which can be still further excised or united at once, at the discretion of the operator. It is the repair and firm suture of this, confining the rectum backwards, that is the essential in the cure of every rectocele, but I question whether it is of much use in the prevention of a cystocele. The accompanying cystocele in cases of bad protrusion needs separate treatment. The usual operation I have done for some years in cases of severe prolapse is, first, a repair of the cystocele by anterior colporrhaphy, with a buried tier-suture of the base of the bladder, so as permanently to contract its capacity and cure all anterior bulging. The suture is a continuous one of the finest silk, carried from urethral orifice to cervix, back again from cervix to urethra, and still back again from urethral orifice to cervix, enfolding more and more of the dilated and redundant bladder, until the base of the bladder and anterior wall of the vagina are perfectly taut and firm. Here the fascia is sometimes recognisable, more often it is not; but the remains of it are taken up with the floor of the bladder in the silk suture. This suture is buried. A separate running silk suture unites the vaginal wound over this. The uterus is then fully replaced, another posterior dissection between the rectum and bladder carried out as I have described. As much of the posterior and lateral vaginal wall as is considered advisable is then removed through nearly the whole length of the vagina. Deep sutures of silkworm-gut are passed to bring the raw surfaces into close apposition, and a separate fine silk buried suture is often used for the fascia only. It may help to explain my description if I show the parts removed in a recent case, occurring about two weeks ago, after the meeting is concluded. The operation is, of course, a minor one, and the wounds heal readily without any suppuration or temperature. By this means the vagina is contracted through its whole length; the recto-vesical fascia is repaired, the bladder is kept up, but the vagina is retained, and no definite function or organ is necessarily lost. I cannot say whether all of the cases operated on in this way will stand the test of time, but so far I have not met with any real failure. In one respect, even as regards the protrusion, I am inclined to think that the method I have described may compare very favourably with that of total extirpation of the vagina. Some cystocele-bulging or impulse was present in the cicatrix of one of the cases Mr. Martin kindly showed me, and this, I think, may be avoided by the cure of the cystocele before repairing the fascia posteriorly. I should like to suggest that even in extirpation of the vagina it might be advisable (if time permitted) to enfold and narrow the base of the bladder by a buried suture before bringing the rest of the wound together. I think that the Society is to be congratulated in having such an original and bold innovation in surgery and such a valuable and interesting paper brought before it by one of our Fellows. As our President as well as his colleague, in thanking him for his communication, I would like especially to notice the fine and virile restraint which has marked his practice. The treatment is, as he has acknowledged, a severe and even dangerous one. He has used it with rare judgment and discretion.

Mr. CHRISTOPHER MARTIN, in reply, said: First let me thank the President and members of the Society for the most kind manner in which they have received and discussed my paper. In reply to Dr. Mansell Moullin, I have never found any difficulty in recognising the fascia and in sewing the edges together. It is a very distinct and definite layer. In reply to Dr. Hodgson, who asked why the bloody effusion broke down into pus, I would point out it was open to two sources of infection—bacteria from the rectum and bacteria from the ulcerated cervix and vagina. Dr. Fenwick asks "Why not leave the anterior wall of the vagina and be content with removing the posterior vaginal wall and sewing up the fascia?" I would point out that this would not cure the cystocele. Ergot and strychnine given with the idea of reducing the size of

the uterus would, I am sure, be perfectly useless in bad cases of total prolapse. Moreover, most of these women are past the menopause. I am interested to learn from Dr. Macnaughton-Jones that Professor Martin, of Berlin, has devised and carried out a somewhat similar proceeding. I appreciate the value of the suggestion of Dr. Macnaughton-Jones that the uterine arteries should be ligatured before the vaginal mucous membrane is dissected off. It would no doubt tend to diminish the arterial bleeding. The most troublesome bleeding comes from the veins of the vaginal plexus, and I do not think that it would prevent this. I am very grateful to the President for his generous remarks. I am pleased to know that he agrees with me in insisting on the importance of suturing the pelvic fascia in operating for uterine prolapse. In all these cases of plastic operations it will be found that the more thoroughly the vaginal mucous membrane is removed, and the more completely the pelvic fascia is brought together, the better will be the ultimate result.

Dr. MACNAUGHTON-JONES read notes of the condition Tuberosa Subchorial Decidual Hæmatoma, and touched on the etiology of the condition as advanced by Breus, Go'dspohn, Newman, Davidsohn, and H. Schroeder. He showed with the epidiascope a specimen of Professor H. Schroeder's of this condition, which he (Dr. Macnaughton-Jones) had recently brought from Professor Fritsch's klinik at Bonn.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD IN THE ROYAL COLLEGE OF PHYSICIANS,  
ON FRIDAY, NOVEMBER 11TH, 1904.

The President, Dr. W. J. SMYLY, in the Chair.

#### SPORADIC CRETINISM.

Dr. KIRKPATRICK showed a child, æt. 4, which at the present time weighs 15 lbs. Two years ago the child was under observation, and then weighed 13 lbs. The child is greatly emaciated and shows little or no signs of intelligence, and has never made any attempt to speak. The skin is clear and soft, and the hair well grown, the characteristic cretinoid aspect being completely absent. There is no history of congenital syphilis, nor are there any well-marked signs of this condition, and though there are some signs of previously existing rickets, there was no evidence of the acute stage of this disease while the child was under observation. No trace of the thyroid gland can be detected by palpation in the neck, and during the last fortnight, while the child has been under thyroid treatment, he has shown some signs of improvement. Dr. Kirkpatrick was inclined to look on the case as a rather anomalous one of sporadic cretinism.

Dr. WALTER SMITH asked, was the possibility of rickets with hydrocephalus considered as a diagnosis, as the symptoms would fit in with that?

Dr. LANGFORD SYMES said that one or two possibilities occurred to him. First, rickets. The head was typically rachitic, with large fontanelles and extreme bossing. There was also some beading of the ribs, though there was a lack of the enormous beading one would expect. Second, there was a possibility of some congenital syphilis. The child's teeth were strongly notched. The abdomen was peculiar, being a very large, protuberant one, and the intestines were apparently a good deal matted. The child was also suffering from great marasmus. There was serious mental defect, and probably some hydrocephalus.

Colonel McNERCE asked, was there any history of consanguinity? He related a case of two first cousins having married, the parents of one being also first cousins. The first child presented exactly the same appearance as Dr. Kirkpatrick's patient. Twins were afterwards born, one like the first child, the other healthy. There was no history of syphilis.

Dr. KIRKPATRICK said he had thought of rickets and hydrocephalus, but since seeing the child first it had

never shown signs of acute rickets, nor was there a history of any acute illness. The condition had developed gradually. Possibly rickets might explain some of the symptoms, but not all. The child was in fairly good health, had no pain, lay quietly in bed, had no fever. He could find no symptoms which would definitely point to congenital syphilis. There was no history of a rash, nor were there any scars on the body. The notching of the teeth went for nothing, as the typical syphilitic teeth occurred in the secondary dentition. Also the child would probably not have remained in its present condition for two years without improving or unimproving. Ten days ago it was put on thyroid extract, and during that period the child had shown signs of improvement. It had shown more intelligence, took more interest in its surroundings, and was more anxious for food.

Dr. TRAVERS SMITH exhibited the four following patients:—(a) A girl, æt. 10, looking perfectly healthy, with no history or signs of rheumatic taint. She had never complained of any cardiac symptoms. A strikingly distinct systolic thrill was felt all over the præcordial area, most marked in the region of the pulmonary artery. The thrill corresponded to an exceedingly loud, rough murmur, most audible in the pulmonary area. The right ventricle was slightly enlarged. A diagnosis of some congenital defect of the pulmonary artery leading to slight stenosis was made by Dr. Smith, who also pointed out that, though the cardiac lesion was unquestionably organic in nature, the murmur was diminished by a full inspiration almost to the same degree as one expects in the case of the so-called pulmonary hæmic murmur. (b) A middle-aged woman with complete loss of perception of tactile, thermal, and painful sensation in her entire skin. The mucous membranes were not affected. The conditions had existed for a week or more. The diagnosis of hysteria was made. She has since greatly improved. (c) A man, æt. 35, who had been admitted to the Whitworth Hospital a year previously suffering from left-sided hemiplegia and hemianæsthesia. Thrombosis of the branch of the middle cerebral artery supplying the right internal capsule was diagnosed, and though a history of syphilis was denied, this was considered the most likely cause. He left hospital after a few weeks very greatly improved. He returned a few weeks ago complaining of typical lightning pains: Argyll-Robertson pupils had developed, and slightly impaired sensation in the feet. The knee-jerk on the left side was still greatly exaggerated, and Babinski's sign was present, whilst the right knee-jerk was almost completely lost. Ataxia was doubtful, even with severe tests. Tabes dorsalis was now diagnosed, thereby confirming the suspicion of syphilis. The persistence of the exaggerated left knee-jerk Dr. Smith considered an interesting point in the case. (d) An elderly woman, who some months ago developed hemi-athetosis affecting the leg, arm, lower part of face, and tongue on right side. There was no history of apoplexy. Dr. Travers Smith had observed her for a fortnight, and came to the conclusion that she was rapidly becoming demented. He considered some variety of cerebral softening to be present.

#### CAISSON DISEASE.

Dr. J. B. COLEMAN made a communication on the subject of caisson disease, as experienced by workers engaged in boring a tunnel for five miles beneath the bed of Lake Erie from and after the year 1897. He mentioned the theories of this disease: (1) Emboli of nitrogen liberated from the blood in consequence of reduced pressure and so obstructing the small vessels and injuring the nerve elements; (2) the toxic effect of oxygen under high pressure; (3) congestion with either acute revulsive anæmia or comparative stasis. The symptoms came on after rapid decompression of one to three minutes. From ten minutes to six hours after reaching normal pressure the patient suffered excruciating pains, usually in his knees, sometimes in shoulders and elbows, rarely in his hips; maniacal attacks supervened occasionally; retention of urine

was common, and in the severe attacks paralysis of the sphincter ani. Paraplegia occurred and lasted for a few hours to months, and in severe cases persisted with the symptoms of spastic paraplegia; transient facial paralysis was seen; an æsthesia extending up to the ribs was common; an intense feeling of pruritus ("the itch") might occur without pains; bleeding from nose and ears; vertigo, dimness of vision, headache, vomiting, and muscular cramps were other symptoms noted. Urgent attacks of dyspnoea ("the chokes") were frequent, during which the patient felt his lungs over-distended; then a cough was set up, and large quantities of gas, seemingly from the stomach, issued from the mouth. Relief from the joint pains and from retention of urine was obtained by a very hot bath. After work the men felt "wearied and bruised," and on returning to the compressed air they became exhilarated and relieved. Except in the most severe attacks the symptoms always abated on undergoing recompression. The highest pressure was 46 lbs. to the square inch.

Dr. WALTER SMITH said the interest of the disease centred in its pathology. The first point was the comparatively moderate pressure which produced the disease. It was sometimes laid down that it requires a pressure of three atmospheres, but this patient had worked under considerably less. The second point was the persistence of the effects; this man was regarded as incurable. Thus a difficulty was raised as to the mechanical theory of causation. It had been proved by experiments on animals that gas embolism could occur, but it puzzled him to understand how a mechanical explanation, especially with a gas like nitrogen, could produce such terrible and long-abiding effects. There was, therefore, some other factor. A direct myelitis was set up, and it was possible that a sudden mechanical disturbance of the pressures might cause not only gas embolism, but also an ebb and flow in the vascular condition. It must cause a shock to the nervous elements, and he did not know what might happen to the protoplasm of the nerve elements. Therefore he thought it premature to suppose that the symptoms were caused by gas embolism only. It was well to examine the converse case, and compare the results of over-pressure with under-pressure, as in balloon ascents or mountain sickness. It was known that below a certain pressure a person would die, owing to diminution of the oxygen tension in the arterial blood. It is not the absolute pressure of the gases, but the increased oxygen tension that is important. There might also be the direct irritant or toxic effect of oxygen gas. As to preventive measures, he thought the method of purifying air and absorbing CO<sub>2</sub> by sodium peroxide should be employed, and the patients provided with it.

Dr. NINIAN FALKNER asked if the presence of marsh gas could account for the symptoms?

Dr. TRAVERS SMITH asked how the purely mechanical theory, namely, that of gas embolism, could be reconciled with the frequent delay of the onset of the symptoms after the return of the workers to normal atmospheric pressure.

Dr. COLEMAN said that his patient got his symptoms worst when going through strata of marsh gas, but got the "chokes" when there was no obvious presence of that gas. In reference to the comparatively small air pressure which brought on the symptoms, the highest pressure the patient worked under was 46 lbs., about three atmospheres. No theory would satisfactorily explain all the symptoms of the disease, and it was not unlikely that two or three conditions were necessary to bring it about. It was likely that the disease was caused by gaseous emboli of nitrogen acting mechanically, or by oxygen from a direct irritant effect. In reference to therapeutics he was not aware that peroxide of sodium had been used, but the method of ventilation was to pump in large quantities of fresh air, the air escaping from the lower end of the caisson. His patient found that when the symptoms were coming on, they were arrested if he went back into the compressed air. Medical locks were in use in well-regulated works; the men were treated

there, and decompression was gradually produced. As to the delay in the onset of symptoms, in some cases they did not come on for hours, though it was likely that any gas which was going to escape from the blood did so almost immediately, but the mischief had already been done to the nerve elements.

#### Dr. G. PEACOCKE described two cases of HODGKIN'S DISEASE

that occurred in twin boys, æt. 4. One of them had died eighteen months after the glandular enlargement first appeared. At the time of his death the glands on the right side of the neck and a few in the right axilla were enlarged. The spleen reached as low as the umbilicus. The red cells numbered 1,300,000 per cm.; hæmoglobin, 15 per cent.; white cells, 8,000 per cm.; differential count—lymphocytes, 21 per cent.; polymorphs, 86 per cent. The other boy, whose illness dated from last February, was still alive, and his general condition satisfactory. Some greatly enlarged glands in the left side of his neck had been removed a few weeks previously. Microscopic examination showed the enlargement of the glands was due to a general increase of the cellular portion of the glands. His spleen was not enlarged and a blood count showed red cells 4,000,000 per cm.; hæmoglobin, 85 per cent.; white cells, 8,500 per cm.

#### WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, NOVEMBER 4TH, 1904.

C. M. TUKE, Esq., President, in the Chair.

#### CLINICAL MEETING.

Dr. P. S. ABRAHAM showed (1) a case of "scleroderma with bullæ and ulceration," occurring in a woman aged 55 years. The progress of this case was remarkable and probably unique, as bullæ, which usually do not occur in sclerodermic integuments, formed about the knees in this patient six months after the onset. (2) A remarkable case of "keloid," the result of a burn from a gun-cotton explosion at Woolwich two years ago.

Dr. A. E. RUSSELL showed a case of "tabes dorsalis" with gastric crises in a patient 42 years old. He evinced very typical symptoms which are of two years' duration, and accompanied by severe gastric crises, being associated with troublesome vomiting, which resist ordinary treatment.

Dr. A. E. RUSSELL also exhibited for Dr. A. P. Beddard (1) a case of "tremors," the patient being a man, 27 years of age, who went through the siege of Ladysmith, where he contracted typhoid and dysentery, after which the tremors appeared at irregular intervals, involving chiefly the hands, and to a less extent the head and lower limbs. Dr. Russell considered this case to be functional in origin, there being no symptoms of organic lesion.

He also exhibited a case of (2) "myositis ossificans" in a man aged 37 years, which had developed slowly since the age of seven years. Bony growths are felt in the muscular system in innumerable positions in the form of bony masses in the tendons and insertions of the muscles, causing great impairment of movement of joints, several of which are ankylosed, rendering him quite helpless.

Mr. A. BALDWIN considered there was some relationship between this disease and pseudo-hypertrophic paralysis, also hæmophilia, and transmitted through the females to the males of the family.

Dr. A. GASTER related that he had a family under his observation in which the grandfather, father, and three sons had the disease, whereas the mother and two daughters had escaped.

Mr. ASLETT BALDWIN showed a case of "tabes dorsalis" with Charcot's disease of tarsus, in a man, æt. 34 years. The disease apparently commenced in 1900, after a slight injury to the feet, and since which time the enlargement of the feet has slowly progressed. He could walk very well until August, 1904, when the right foot suddenly commenced to

turn inwards, necessitating the wearing of irons to keep the foot straight. He exhibits well-marked symptoms of locomotor ataxy.

Mr. G. A. GARRY SIMPSON showed (1) a case of "clonic spasm of soft palate" in an unmarried woman, *æt.* 40. This affection arose about a year ago, when she received a severe shock owing to the sudden death of a brother. The contractions of the velum palati are at the rate of 60 per minute, and are accompanied by a clicking sound audible to the patient and to those around her. There is no irritation of nose or pharynx to be discovered, and the muscle principally involved is the levator palati supplied by the facial nerve; (2) "pharyngomycolosis leptothrix," the subject being a married woman, *æt.* 27 years, whose attention was first drawn to the disease by having a constant disagreeable taste, and having hard, white, chalky substances on the tonsils. The disease is associated with the leptothrix fungus, a specimen of which Mr. Garry Simpson exhibited under the microscope. He considered that the leptothrix forms a nucleus in the tonsillar crypts and accumulates altered cells and debris.

Dr. BALL was of opinion that local treatment was of very little use, he having tried all kinds of germicides, which only led to disappointment. He considered the leptothrix as accidental, and not the cause of the disease.

Dr. NEVILLE WOOD asked whether the disease has become more common of late, as recently he has had a number of such cases under his observation.

Mr. COLE MARSHALL showed Dr. E. P. Paton a case of "misplaced testicle" situated in the left side of the perinæum. The testis is surrounded by a hydrocele, with a hernia, probably sciatic.

Mr. DONALD ARMOUR showed (1) a case of "ankylosis of jaw" in a girl, *æt.* 24 years, who is one of six children, who are all living and well. Her jaw has been ankylosed since infancy, and the jaws cannot be separated. The teeth (two central incisors) have been broken to enable her to get food into the mouth, and she masticates with the tongue. There is no paralysis of the masseter or temporal muscles. No cause can be attributed for this condition, unless possibly a fall downstairs in infancy, which has left a scar on the chin. (2) "Parotic swelling," commencing in a man ten weeks ago, associated with pain at base of zygoma, which was periodical. Two weeks ago he began to have difficulty in opening the mouth. The swelling is limited by the parotid fascia, and is slowly increasing, and the paroxysms of pain are increased with a point of tenderness over the base of the zygoma.

Dr. PARDOE did not think the swelling to be connected with the temporo-maxillary joint, although this joint is specially liable to attacks of gonorrhœal synovitis. He considered it to be a case of suppurative parotitis.

Mr. BALDWIN also considered it to be a case of suppurative parotitis, and suggested excision of the gland and examination of the pus.

Dr. ARMOUR also showed (3) "hypertrophic pulmonary osteo-arthropathy" in a man suffering from syphilitic synovitis of knee-joint.

Dr. A. M. ROSS SINCLAIR showed an interesting and rare case of "paralysis of the cranial nerves," in a woman 29 years of age, who first complained in the beginning of September of pain in swallowing solid food, irritable cough, and hoarse voice, with loss of weight. The right side of tongue, soft palate and vocal cord on same side were completely paralysed, together with the sterno-mastoid and trapezius muscles. The patient's sensory, motor, and reflex functions are otherwise normal. The lesion, he considered, was probably due to syphilis contracted seven years ago, and there is probably a gummatous thickening of the membrane at the base of the medulla. The patient is improving under specific treatment.

#### THERAPEUTICAL SOCIETY.

At the third annual meeting of this Society, held at the Apothecaries' Hall, Blackfriars, on October 25th,

1904, Sir WILLIAM THISELTON DYER in the Chair, Sir Lauder Brunton was elected President of the Society, and Dr. H. French Assistant Secretary. The thanks of the Society were given to Sir W. Thyselton Dyer, for his services as President of the Society from its commencement.

In response, he said that under the Presidency of Sir Lauder Brunton the Society was certain to prosper. It was then agreed that in future candidates should be elected by the general meeting of the Society.

Dr. ARTHUR HARRIES then read a paper on "Some Applications of the Continuous Current," which he said might act either mechanico-physically by cataphoresis; electro-chemically, termed electrolysis; or electro-physically, called catalysis, and he gave illustrations of benefits from each of these actions in cases of rachialgia, arthritic and other affections, also in cases of stricture, disease of prostate and lupus.

Dr. GEORGE CRICHTON read a paper on the "Metric System in Dispensing," showing the great inconvenience of the present system, which consists of three entirely different measures—the pound, the drachm, and the fluid drachm and minim, causing much difficulty in correlating these. In prescribing, the gramme is nearly one-quarter of a drachm, and one-fifth of a centimetre is nearly three minims. Mistakes owing to the wrong position of a decimal point ought not to occur if proper care is used in writing prescriptions.

### France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 20th, 1904.

#### A SIGN OF PHELGMONOUS TONSILLITIS.

PROFESSOR VINCENT, of the military hospital of Val de Grâce, has described a new sign of quinsy—contraction of the pupil on the same side as the phlegmon. The patient standing in an average light, it is easy to observe the inequality of the pupils. It is true that this unilateral myosis also accompanies other forms of sore throat, but it is very inconstant and but slightly perceptible. It is, on the contrary, very frequent in phlegmon of the tonsil, and persists with the malady even several days after the abscess has been evacuated. The explanation of this phenomenon is embarrassing. The contraction is probably the result of a special reflex, and this reflex originates in the velum of the palate, for it appears only when that region is affected. According to one authority, Meckel's ganglion and the ophthalmic ganglion are, in some individuals, in direct communication one with another, and that fact could explain that a painful unilateral inflammation taken by the palatine nerves might, in a reflex medium of which the spasmodic centre is Meckel's ganglion, produce the contraction of the iris on the same side.

#### TREATMENT OF BURNS.

The fundamental division of burns is as follows:—(1) The burn is recent; (2) the burn has existed for several days and has been modified by more or less prolonged suppuration. As regards the former, the accident has just occurred, and no application has yet been made. What is to be done? The treatment will differ according to the gravity of the lesion and the degree of the burn.

If it is a case of the first degree (erythema), an application of vaseline and cocaine (1-100), covered with a sterilised compress, will be sufficient to relieve the pain. If the burn be of the second degree, if it be accompanied by phlyctena, these should be scrupulously respected. The common practice of piercing the skin to let out the serosity should not be followed. It is sufficient to cover the region with a compress wet with a solution of picric acid (1-100), and finally a thick layer of carded wool maintained with a bandage. This dressing should not be disturbed for three or four days. If the bullæ are already opened the treatment will be

that of the third degree, or that of ulceration, which consists in antiseptic washing of the parts and applications tending to provoke the renovation of the epidermis.

The antiseptics of the region consists in carefully cleansing the immediate healthy skin and the lesion itself. If the patient is courageous enough, this operation can be done without anaesthesia. But if the lesions are extensive and the patient cannot support the suffering, it is preferable to have recourse to local anaesthesia with stovaine, or, better still, to general anaesthesia. The bullæ will be completely opened with scissors, sterilised in the flame, so as to lay bare the wound. The ulcerations will be carefully washed with soap and warm water so as not to lacerate the tissues, and the soap removed by compresses of boiled water, and, finally, the region will be washed with ether and alcohol. The wound will then be covered with a dressing of picric acid solution, as in the first case, and a thick layer of cotton wool. The dressing will not be removed for four or five days, when the ulcerations will be generally cicatrised or partly healed. Care must be taken not to take off the dressing roughly for fear of destroying the new skin.

In case of extensive burns, therapeutics are generally of little avail. It is the general condition of the patient that should be attended to. Warm baths, according to the Hebra method, may be of some use. Burns of old standing are those badly treated at the beginning and arrived at the stage of suppuration. They are no longer burns, but ulcers without tendency to cicatrise. The region should be carefully cleansed as above and for three or four days oxygen water (12 volumes) should be applied. In certain cases oxygen water is ill tolerated; it can be replaced by compresses of boiled water. After this period of wet dressing, when the wound will have been properly cleaned and granulations will have begun, peroxide of zinc (ectogan) will be applied.

The wound generally heals very rapidly under this treatment.

#### TREATMENT OF HYDROCELE.

Withdraw one or two drachms of the liquid and inject half a Pravaz syringe of a solution of adrenalin (1-1,000). Repeat the operation eight days after. By this method a rapid cure is effected.

#### ANOTHER TUBERCULOSIS CURE!

The explorer, Dathan de Saint-Cyr, whose researches on the cure of consumption by a West Indian plant have been frequently referred to, has just placed his thesis on the subject before the Paris Académie de Médecine, which will investigate the claims made for the remedy by its author.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, November 19th, 1904.

At the Medical Society, Hr. P. Marcuse showed a boy suffering from

#### MICULICZ'S DISEASE,

so named from having been first described by that surgeon. The lachrymal glands, as also the whole of the salivary glands and those of the heart—the parotid, the submaxillary, the sublingual and Nuhn's glands—were all enlarged and formed well-defined rather soft tumours, not painful, and easily movable under the skin. The disease began three months ago with pain in the head and neck, and the day after the lumps were felt. The lachrymal secretions had ceased entirely, and the salivary secretion almost; the small quantity of salivary secretion contained no cyanid of potassium. The urine was free from sugar, and the blood was normal. There was not much distress. The speaker thought the cause was some infection. Therapeutically potassium iodide arsenic, and massage had been advised.

Hr. Westenhoefler spoke on

MEAT INSPECTION WITH REGARD TO TUBERCULOSIS.

He said that in a previous address he had stated that the flesh of tuberculous animals contained no tubercle bacilli except in the cases of acute miliary tuberculosis, and he was now in a position, as a result of his continued investigations, to support this view. He implanted pieces of muscle from tuberculous animals into guinea-pigs, which were known to be extremely susceptible to tuberculosis, but always with negative results. Of seven animals inoculated from animals suffering from acute miliary tuberculosis four only became diseased.

When the direct implantation of the flesh of tuberculous animals into guinea-pigs gave only a negative result, it was not to be wondered at if feeding them with such flesh set up no disease.

He suggested, therefore, that only the flesh from tuberculous organs (bones and joints), as well as the flesh of animals suffering from acute miliary tuberculosis, or animals much emaciated from tuberculosis, need be destroyed, and that the flesh of animals suffering from internal tuberculosis was fit for food. If axillary glands or those of the legs were diseased, the whole of the quarter need not be destroyed.

According to recent regulations, meat from the country that had undergone veterinary inspection at the place of slaughter did not require further inspection before being sold in the city. Independently of the country veterinary not being so well skilled in meat inspection as their specialist *confère* in the city, he was also to a certain extent dependent on the person employing him, and he might, therefore, be not quite so strict as he should be. As a matter of fact, 1 per cent. of the meat inspected in the city control stations that had been killed in the country had to be rejected. Country slaughterhouses should be in central localities, and only fully paid inspectors independent of private practice should be appointed. Until that was done meat from the country could not be beyond suspicion.

In the Dermatological Section of the Naturforscherversammlung, Hr. Strebel spoke on the use of CATHODAL RAYS AS A SUBSTITUTE FOR RÖNTGEN AND RADIUM RAYS.

In their action the speaker said they resembled radium rather than X-rays. In two cases of cancer, and various patches of lupus, ray-emanation of eight to ten minutes sufficed to cause moderate reaction, and, on this, absorption of infiltration. The advantage of this process lay in its being able to replace the very expensive and hardly procured radium. He then described the advantages of his photocaustic, which was a useful complement to Finsen light treatment, one advantage being that after cauterising to the third degree the cutaneous nerves were destroyed, so that when the patient woke up after the operation she did so free from pain. Photocaustic could also be employed in the consulting room by making use of a cooling apparatus that he had devised. In three cases of severe and intractable X-ray ulcer, that had resisted all treatment for a year and longer, healing was brought about in four or five weeks by the use of the photocaustery. The glow-light treatment in diseases of the urethra was perfectly ideal; any stage of inflammation could be set up at will, from simple erythema blistering, and with the certainty that after the artificial inflammatory process had subsided there would be no danger of subsequent stricture. The pure light reaction was the strongest; with later reaction the rays must be used longer.

Mrs. D. Lydia Rabinowitsch, who, in consort with Dr. Max Köch, had examined a large number of birds from the Zoological Gardens, spoke on

#### BIRD AND MAMMALIAN TUBERCULOSIS.

Of 200 birds of the most varied kinds, about 25 per cent. were tuberculous. The disease appeared to commence in the digestive organs. Pulmonary tuberculosis was more frequent than it had been understood to be. The danger of infection from bird to bird was not great; it lay mostly in eating the excreta of diseased animals, or feeding on infected rats or mice. The bacilli of bird tuberculosis might invade mammalia. Mammalian tuberculosis was found in two eagles; this form had

hitherto only been met with in parrots. The culture of pathogenic properties of bird and mammalian tuberculosis were different. Transitions and certain variations in toxic property were observed in some strains. Attempts to change one kind into another by experiments on animals were but rarely successful.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 19th, 1904.

### ORTHOSTATIC TACHYCARDIA.

At the last Breslau meeting, Thomayer recorded three cases of tachycardia in which the pulsations were normal when the patients lay down, but immediately the body was raised into the normal attitude the tachycardia was aggravated. This being a rather unusual form of the morbid condition, he has designated it orthostatic tachycardia, which depends for its origin upon some weakness at the bulbar centre, producing lowering of the arterial blood-pressure on the vessels when the body is erect. He is of opinion that this orthostatic tachycardia is particularly confined to the origin of the vagus in the bulbar centre, which is proved by intoxicants acting on this centre.

In the horizontal position the liquor cerebro-spinalis, which seems to be the exciting cause, is allowed to be more distributed, but when the head is raised the pressure is increased and produces the morbid symptom. In support of this hypothesis he quoted from a number of experiments performed on healthy persons where the pulsation is greatly reduced immediately the head is depressed below the pelvis. In this position the pulsation is slower than in the horizontal and still less than in the vertical position.

### OTOGENIC MENINGITIS WITH RECOVERY.

At a meeting of the Naturforsch. Fischer related the history of a case of meningitis in a young man, æt. 19. The illness commenced with great pain in the head, vertigo, and loss of consciousness, but no convulsions or vomiting. On the second day of the disease the temperature rose to 38.9° C. (102° F.), the pulse 100 with a difference in the size of the pupils, left facial paralysis, stiffness in the neck, Kornig's symptom, and a very high state of hyperæsthesia in the sensory nerves. There was also otitis with rupture of the tympanum.

Puncture of the membranes of the spine in the lumbar region emitted a cloudy cerebro-spinal fluid under great tension. The fluid was rich in leucocytes, but no organisms could be found either by culture or inoculation. After this the patient gradually improved for five days, when the puncture of the lumbar region was repeated, by which a clear fluid was obtained this time. On the sixth day a new complication appeared in the form of typical croupous pneumonia, which reached a crisis on the tenth day of the disease. After this period he gradually recovered, and is now quite well.

Such prominent symptoms could not be explained on any other ground than a secondary meningitis from the otitis, and forcibly proves that all pustular centres should be cleared out as soon as possible.

### BLOOD-PRESSURE.

Hürtle gave a historical account of the experiments on, and writers who have attempted to elucidate, this subject. Pressure and velocity have engaged the attention of Volkmann, Ludwig, &c., who conducted their experiments with chromic colours, which are rather fallacious as the resistance is an uncertain factor. If velocity, index pressure, and resistance be represented by V, I P, and R, the equation for velocity would be  $V = J(P R)$ , but as we know so little about the resistance the blood meets with on its course, both internal and external, the former depending on the viscosity of the blood, the latter on the dimensions of the vessels. The greater the viscosity the greater the internal resistance; and as the normal blood of the dog is four to five times that of distilled water at the same temperature, by means of this

value we can arrive at the external pressure in the equation which may be confirmed by the bromindex. Hürtle gave a few formulæ from authors on the subject, which were quite erroneous, and demonstrated one case where he proves that the velocity of the blood in the artery falls quicker than the pressure.

### DEAFNESS IN SCHOOL.

Konig, as medical officer of health in Westphalia, has selected a particular small town in his area for exact observation, and gives us the following:—From 787 children, 289, or 36.7 per cent., had normal hearing; 498, or 63.28 per cent., had defective hearing; 432, or 54.8 per cent., being bilateral. In analysing the defectives 9 per cent. had discharging ears, 17 per cent. enlargement of the pharyngeal glands, 14 per cent. enlarged tonsils, while 60 per cent. suffered from catarrh of the Eustachian tube and middle ear. In the whole school 15 per cent. of the boys would be exempted from military service owing to deafness. Only 2½ per cent. were actually conscious of deafness or any defect about the ears. He thinks the State should see to the treatment of these children as part of its duty.

### EOSIN LIGHT TREATMENT.

With the advances of light treatment every device seems to be resorted to with satisfactory results. Pick, of Prague, has obtained all the beneficial results if not better than those accomplished by the Röntgen rays. The morbid part is painted over with a 1 per cent. solution of eosin and then exposed to the sun's rays.

The long series of cases treated in this way includes twelve of lupus, five of trichophytis, three of sorofula dermis, and one case of tuberculosis cutis verrucosa, with ulcus rodens. In the lupus cases the inflammatory appearance receded in a very short time after commencing the treatment and consequently the hypertrophic tissue soon disappeared. In no case had he yet met with any bad after effects. The trichophyte cases healed in a few days, while the ulcus rodens lingered about a week after, before perfect healing was accomplished.

## The Operating Theatres.

### LONDON HOSPITAL.

OPERATION FOR SINUS FOLLOWING APPENDICULAR ABSCESS.—Mr. F. EVE's patient was a boy, æt. 15, who had been operated on for appendicular abscess in the country more than a year ago. The sinus having persisted, he had been operated on two or three times subsequently. Mr. Eve remarked that a sinus following an appendicular abscess may be due, first, to the sinus communicating with an appendix which had been perforated, the appendix not having been destroyed by the abscess; secondly, to a fecal concretion which had not been removed when the abscess was evacuated; thirdly, to a silk suture when the appendix had been removed, therefore catgut sutures should always be employed; fourthly, the abscess may have burst into the cæcum or other part of the bowel; fifthly, the original disease in the appendix may have been tuberculous—a tuberculous sinus persisting after the operation; sixthly, as a rarity the original disease may have been actinomycosis. It was often stated, Mr. Eve pointed out, that the appendix was usually destroyed or rendered obsolete in those cases in which abscess formed, but this was by no means always the case. Therefore, patients should be warned that a fistula may follow in those instances in which it has been found impossible or inadvisable to remove the appendix. As regards the operation itself, he said the most important point was to open the abdomen sufficiently freely by an incision at a distance from the fistula. If the fistula

were laid open directly, the peritoneal cavity might also be opened at the same time and thus infected from the fistula; and, further, the bowel would probably be found adherent to the parietes and might be injured. The method of making the incision at a distance from the fistula allowed the surgeon also to make a thorough inspection of the interior of the abdomen and to separate adhesions when necessary before the sinus itself was interfered with. In the case under observation the fistula was situated a little above and internal to the anterior superior spine. An incision was made to the inner side of the fistula and an inch and a half from it. The peritoneal cavity was freely opened, and the area of operation packed off with gauze from the general peritoneal cavity. The fistula was then laid open, and it was found to terminate in the distal end of an appendix about an inch long, which apparently had been separated from the main body by sloughing. The proximal part of the appendix had apparently been removed at a former operation, as the stump was found attached to the cæcum. The sinus and portion of appendix were removed. The wound was then thoroughly cleansed, the packing removed, a gauze drain inserted, and the wound closed.

#### ST. PETER'S HOSPITAL FOR STONE.

A CASE OF COMPLETE PROSTATECTOMY FOR ENLARGED PROSTATE.—MR. THOMPSON WALKER demonstrated a case on which he had performed complete prostatectomy six weeks previously. Before operation the patient, æt. 66, had suffered from complete retention of urine for five years, and previous to this from increasing frequency of micturition for four years. During the five years previous to operation he had passed his catheter four times daily, but not at night. During the last month he had frequent desire to micturate and had passed his catheter about every hour and had caused bleeding on each occasion. There was recurrent left epididymitis. His prostate per rectum was moderately enlarged, rather soft and movable. With the cystoscope a well-marked projection into the bladder was seen. There was slight cystitis, but no vesical stone. The bladder was first washed out until the fluid became quite clear, it was then distended with twelve ounces of boracic solution and the coudée catheter plugged and left in position. On opening the bladder above the pubis at the operation, a well-marked collar-like intra-vesical projection of the prostate was felt with the left forefinger in the rectum pushing the enlarged prostate upwards. The prostatectomy was commenced by scraping through the mucous membrane covering the most prominent part of the collar; the mucous membrane stripped off readily before the finger, which was then passed onwards between the prostate and the vesical sphincter; the finger then slipped between the fibrous sheath and the capsule of the prostate and was swept round the extra-vesical part of the right lobe; without removing the finger from its position between prostate and sheath it was swept across the middle line, passing behind the prostatic urethra and left lobe of the prostate. The enucleation was continued by raising both lobes with the finger so that they were separated from the sheath as far as the membranous urethra. The prostate still remained attached at the junction of the prostate and membranous urethra and along the middle line anteriorly. By forcing the enlarged gland upwards these connections

were torn through and the prostate was projected into the bladder by the forefinger. A pair of sharp toothed forceps were introduced into the bladder, and grasping the prostate removed it from the suprapubic wound. The nozzle of an irrigator was then connected with the catheter, which still remained in position, and very hot boracic lotion was introduced into the prostatic cavity and bladder and welled up through the suprapubic wound. The lotion at first was blood-stained, but very rapidly became quite clear, and there was no further bleeding. A large drainage-tube three-quarters of an inch in diameter with a side opening near its lower end, was then introduced into the bladder. The bladder was again irrigated and the catheter removed. The rectum muscles were brought together by a single stitch and two other skin stitches were introduced. There was no collapse after the operation, and no further bleeding. Irrigation of the bladder was commenced twenty-four hours after the operation, the drainage-tube being washed out with fluid from the irrigator, but not removed. In forty-eight hours irrigation through the urethra was commenced without the aid of a catheter, and was repeated daily. A little urine was passed along the urethra on the twelfth day after the operation. From the fourteenth day urine came regularly by the urethra in increasing amount. The suprapubic bladder wound closed on the twentieth day, and the patient left the hospital four weeks after the operation. He is now, six weeks after the operation, in perfect health. His stream, as was seen at the demonstration, was powerful, commenced at once, and did not dribble at the end. He makes his water three times during the day, and does not rise at night unless he drinks beer, after which he gets up once. His urine is still slightly cloudy. Examination of the rectum shows a loose empty sac in place of the prostate; below this the median ridge of the membranous urethra is readily felt, at the upper end of which a small nodule the size of a split pea can be detected.

Mr. Thomson Walker's remarks on this case will appear in "Operating Theatres" of next week.

#### Trinity College, Dublin.

THE following have passed the Final Examination in Medicine—Section A, Michaelmas Term, 1904:—Ralph S. Oldham, John du P. Langrishe, John C. P. Beatty; Francis R. Coppinger, John W. Tomb, equal; Robert B. Jackson, Thomas O. Graham, Thomas H. Peyton, Francis O'B. Ellison, Thomas J. Cobbe, Henry D. Drennan, Edward Gibbon, Michael P. Leahy, Thomas L. de Courcey; Joseph H. Elliott, Dudley F. Torrens, equal; Basil G. Brooke, Daniel M. Corbett, Reginald Holmes, equal; John Murdoch, James E. M'Farlane, Ernest D. Caddell, Francis Casement, Joseph P. R. Poch, George E. G. Vickery, Joseph C. A. Ridgway.

#### Conjoint Examinations in Ireland.

DIPLOMA IN PUBLIC HEALTH EXAMINATION, AUTUMN, 1904.

CANDIDATES have passed this examination as under-noted:—*Honours*.—John Arnallt Jones, M.D. Durh.; M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond. *Passed*.—Samuel John James Kirby, L.R.C.P. Ed., M.R.C.S. Eng., L.S.A. Lond.; Frederick Charles Willmot, L.R.C.P. and S. Ed.; James Wood, M.B., Ch.B. Victoria; Thomas James Wright, L.R.C.P. and S.I., R.A.M.C.

#### Royal College of Surgeons in Ireland.

*Dental Examination*.—The following candidates having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College: L. Ellenbogen, B. Jackson, W. Matthews, and J. J. Murphy. The following candidate passed the primary part of the examination:—T. J. Bradley.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 23, 1904.

**SWEDISH PHYSICAL CULTURE AND UNQUALIFIED MEDICAL PRACTICE.**

THE medical profession is called upon yearly to face new forms of competition by unqualified persons. The evil has recently assumed a number of more or less subtle and semi-scientific disguises. The beauty doctors, for instance, study medical books on skin, hair, and minor surgery; and they proceed to deal forth the flimsy knowledge thus gained at exorbitant rates to credulous clients. The results are no less disastrous than pathetic. Highly skilled and honourable members of the medical profession, who have fulfilled all the terms demanded by the State, as a condition of legal qualification, are condemned to lives of prolonged struggle, and often of actual penury. On the other hand, owing to the defectiveness of the laws and to the listless apathy of the medical profession, the quack flourishes apace, and piles up wealth at the expense of the health, and sometimes of the lives, of his victims. A Bond Street beauty doctor, to take a concrete instance, has lately formed her business into a large limited company, with branches in many parts of the Kingdom. In the same street a well-known hair-dresser makes appointments and receives guineas for consultations upon the hair. One grave aspect of the matter is that these abuses show no sign of decrease. The public has not yet learned to assess medical science by its successes rather than by its failures, the latter of which clearly open the door to the quack. In the matter of electrical treatment medicine has achieved great strides within the last few years. These advances, among which may be mentioned X-ray therapy, electric batteries and the high-frequency current, have at once been seized upon by a horde of unqualified persons, who advertise widely as being willing and able to cure a number of diseases at various homes, institutes or private establish-

ments. The General Medical Council professes itself powerless to do anything towards stemming this current of illegitimate practice. That august body does not venture even to draw up any recommendations or suggestions to the Privy Council or the Government, with a view of defending the interests of the public no less than of the medical profession in a matter vital to the interests of both. The British Medical Association has made various hitherto futile efforts to promote discussion. The Colleges and other qualifying bodies make no attempt to defend the professional rights and interests of their former pupils. Often where a little plain speaking on the part of prominent men in the profession would nip a threatened evil in the bud, the words of warning remain unspoken. In the case of the recent midwives legislation, for example, the united protest of a score of leading men in the medical world might readily have saved the profession from the indignity of being faced with another set of unqualified practitioners, recognised and legalised as they now are by the State. So far from opposing the step, it has been publicly upheld and supported by various prominent consultants who are obviously out of touch with the thoughts, wishes, and aspirations of the general practitioner. One of the most recent attempts to foist upon the British public a new set of unqualified competitors is the proposal to found a college for the teaching of physical education after the model of the Royal Swedish Institute of Sweden. The Bishop of Bristol presided, and the chief apostle and advocate of the project was a Miss Theodora Johnson, who presides over the destinies of a Swedish Institute in Bristol. The lady urged that a national college should be established, with a charter to receive both men and women. The objects would be, as in Sweden, to license massage, and to teach hygiene and physiology. Sir William Church, who was present, pointed out that, in his opinion, the physical deterioration was due to poverty rather than to lack of knowledge of hygiene and systematic exercise. Sir Lauder Brunton received the proposal with faint praise. It would have been more reassuring to the medical profession, and more helpful to the public, had both these gentlemen condemned the proposal in the unsparing fashion it deserves. If they care to inquire into what is going on at their doors, they will find that Swedish massage practitioners are quartered in some of the best streets of the West End of London, where they are carrying on a flourishing practice. Now or never is the time to settle whether this new race of unqualified competitors is to invade our towns. To a great extent this question could be disposed of by the medical profession, were it able to speak out with clear and united voice. Meanwhile we devoutly hope and trust that medical men of all ranks will henceforth decline to have anything to do with this unclean thing, now that its real nature has been clearly and emphatically stated in the columns of a medical journal.

## SUTURE OF THE HEART.

It is less than nine years since the first recorded attempt was made to treat a wound of the heart by suture. Though unsuccessful, its example was soon followed, and the general result has been so good that it is now regarded as the duty of a surgeon, when called to attend a patient with a wounded heart, at once to cut down and attempt to suture. There are, in fact, at present sixty cases of this sort on record, with no less than twenty-three recoveries. This gives a recovery-rate of 38 per cent., instead of a rate, in cases where suture was not performed, certainly not exceeding 10 per cent. The great majority of the wounds treated were caused by stabbing, but of five gunshot wounds of the heart two have recovered. The usual method of exposing the heart is to cut through two or three ribs some inches from the sternum, and bend the flap thus formed to the right, fracturing the cartilages close to the sternum. The pericardium is then opened, and the heart steadied with the left hand while the stitches are inserted. If necessary to check bleeding, the little finger may be thrust into the heart wound during the passage of the needle. It was formerly held that the stitches should only be inserted during diastole, but recent operators think this an unnecessary precaution, and, indeed, often the pulsations of the heart are so irregular as to render the distinction of diastole and systole impossible. It is advised, too, that cessation of the heart's movements should not interrupt the insertion of the sutures. With a quiescent heart, the work can be concluded in a short time, and a little rhythmical manipulation will then probably be sufficient to restore the cardiac movements. An interesting question arises as to the advisability or otherwise of taking elaborate antiseptic precautions. It is obvious, on the one hand, that time may be a matter of urgency, and that no unnecessary delay is to be made before reaching the injured organ. On the other, it is of the utmost importance that the parts should not be exposed to septic infection. In one unsuccessful case recorded by Dr. J. H. Gibbon, of Philadelphia, he believed his failure was due to the delay entailed in cleansing the seat of operation. He concludes that with patients who are in imminent danger it is wise to expose and repair the heart with the least possible delay, while with others who have lived some hours after the injury, or in whom symptoms are not so urgent, time should be taken to practise precise antiseptic precautions. In the great majority of cases recorded the ventricle—left or right—was the part wounded. Curiously, considering its relation to the chest-wall, the left ventricle suffered more frequently than the right. Only two cases of wound of the auricles are mentioned, and in each case a fatal result followed. Considering the previous mortality of wounds of the heart, the results of surgical interference are very encouraging, and the improvement in surgical *technique* which is sure to follow increased practice should give still better prognosis in this serious condition in the future.

## SANITATION AND ART.

WHEN the history of the nineteenth century comes to be written, not the least striking among the many notable features to be recorded will be the development of the science of hygiene that characterised the latter half of its course. Before the Public Health Act of 1848 hygiene as a recognised communal obligation could hardly be said to exist, the previous enactments having been generally conceived in haste to meet exigencies, and more honoured in the breach than in the observance when those exigencies had passed. Certain glaring nuisances were provided for by legislation of one kind and another, but no consistent, enlightened, or far-seeing body of regulations, or provisions against the evils of human aggregation, were in force. Even to-day sanitary science is only in an embryonic condition, consisting, as it does, chiefly of a patch-work of bits from other sciences and a number of still empirical deductions made from them. Still, it has already definite results, and unquestionably hygiene has come, not only to stay, but to make itself of far more weight in the community. Till now the sanitarian has been looked upon by the majority of people as rather a bore, and as his teachings and advice run counter to many cherished traditions and privileged prejudices, it can hardly be a matter for wonder that public appreciation of sanitary science has not been of a very enthusiastic character. The knighthood just conferred on the London County Council's Medical Officer of Health may perhaps be taken as a presage that in future the man who lives to save lives and preserve health will be considered as worthy a candidate for public reward as is the man who kills the most of the country's enemies, or he who brews the most beer. In spite of its many benefits to society, however, hygiene is still unpopular, and till that unpopularity has worn off it will be difficult or impossible to establish those conditions under which people may live together comfortably and happily without being a source of danger to their neighbours, or themselves subject to many kinds of preventable dangers. It has been said that care for sanitation is the last teaching that reaches the civilised, and if this be so, the sanitary arrangements and institutions of a nation may be taken as a gauge of its general advancement in the comity of nations. But there is another teaching that comes late in a nation's life, and that can be of inestimable service to sanitation if sympathetically allied with it—we mean art. Art can only be developed when the more immediate necessities of existence have been supplied and a margin of the nation's resources can be diverted from the more pressing business of fighting enemies and obtaining food, and though the British people are not in themselves an especially artistically disposed people, they have already evolved a more than creditable school of native art, and are more or less capable of being influenced by it. The failure of sanitation to take hold of people's imaginations and enlist their sympathies has been

Due to the facts that its teachings have been formal, and its influence has been for ugliness. Doubtless it is difficult to a new science which is essentially utilitarian in its object to appear ready-garbed in attractive guise, but we feel sure that while yielding nothing in principle, hygiene would be made far more acceptable if it came linked with art. The civilising influence of sanitation, too, would be greater, and art loses nothing in dignity by being useful. In matters of dress the clothing best adapted to the physiological requirements of the body is generally objected to by people to whom it is recommended, because it is not becoming, and not unnaturally the owner of a pretty house resents having its lines broken and its appearance spoiled by outside soil-pipes—even by the most irreproachable plumber. Waterworks spoil many a rural scene; ventilating-shafts deface the finest streets, and rooms without carpets, curtains and pictures are cold and unattractive. What is first needed is a standard of taste and artistic perception in sanitarians, so that their creditable enthusiasm for the cause they have at heart may have increased enthusiasm with their fellows, and what is secondly needed is some artist who can do for sanitation what Morris did for house decoration. That sanitation should be synonymous with ugliness to the public mind is a vast pity, and we venture to think that the antagonism is more plausible than real. The truth would seem to be that sanitarians have been bent on producing a standard of scientific and practical excellence in the articles and institutions with which hygiene concerns itself, and that they have not yet had time to introduce the element of elegance and refinement into their construction. The public, on the other hand, have already had their eye trained to look for beauty in the objects that surround them, and objects like drain-pipes, that have no pretence to beauty, repel and disappoint them. Now, it is well recognised that art that is developed merely in response to the demands of commerce and manufacture never can secure the same height of greatness and originality as if left untrammelled by such considerations, but, on the other hand, it can be very usefully employed as an auxiliary in the sterner aspects of life when it has, independently and for its own sake, already reached the standard it has attained in England to-day. There are plenty of artists and plenty of sanitarians; the two only need take counsel together, and sanitation may become as popular as Bridge, and eventually even find itself in a position to "snatch a grace beyond the reach of art." For the present we should be satisfied if it were able to snatch some of the graces within its reach.

### Notes on Current Topics.

#### Insects as Plague-Carriers.

THE discoveries of Manson and Ross with regard to the rôle of mosquitoes in disseminating malaria and filaria opened up a line of research in the propagation of disease that had up to that time been

almost unthought of. Their brilliant results have encouraged a host of workers all over the world, and it is possible that too much may be now attributed to insects and too little to other agencies unless absolute and demonstrative proof is demanded in every case of putative transmission. For instance, it has been somewhat hastily assumed that as the rat is known to suffer from plague, and is also known to be infested with fleas, these fleas are very likely the mediate agents of plague-transference from rat to man. A paper was read at the September meeting of the Manilla Medical Society by Maximilian Herzog, of the Government Laboratory in the Philippines relating the results of his attempts to fix the responsibility of these insects in the matter. His first experiments were directed to ascertaining whether fleas from rats would bite man, and after a hundred attempts to induce them to feed on his own hand he came to the conclusion that the fleas that live on rats in Manilla will not bite man. Then he tried to see if fleas fed on plague-infected rats would infect guinea-pigs with the disease. The guinea-pig had part of their backs shaved and infected fleas applied, but in no case could he obtain transmission of plague by this means. Herzog next endeavoured to discover if head-lice could act as carriers of contagion, and finding some alive on a plague patient who had died, he was able, by grinding them up and inoculating broth tubes with the resulting mass, to isolate plague bacilli in pure culture from the culture that ensued. His final opinion was that fleas were only remotely responsible for transmitting plague, if they were responsible at all. There appears, however, to be more than one variety of rat-flea, and some of the rarer kinds do bite man, but, on the whole, it must be conceded that work such as that of Herzog suggests a possible doubt as to whether some tropical enthusiasts may not have been somewhat inclined to jump at conclusions instead of laboriously verifying every step on the way. At the same time it is only right to add that the earlier experiments on the infection of healthy rats from their plague-infected fellows in adjoining cages appeared convincing as to the agency of fleas as carriers, to say nothing of the cases in which coolies contracted the plague from handling dead rats. Fortunately, in any case, prevention consists in killing the rats which act as hosts alike to fleas and to lice.

#### Vitality of Germs in Water.

WHILE it has long been known that water, even apparently pure, may act as the carrier of disease germs, it has generally been thought that their vitality gradually decreased with time, and consequently that the danger from an infected water was merely temporary in character. It was stated that though pathogenic germs continued to live for a short time in pure water, yet they tended to multiply but little, if at all. Many observations had been made which seemed to give a solid basis to this belief. For instance, Bolton

was led to conclude that the typhoid bacillus requires a considerable quantity of nitrogenous material to render water habitable, and that in ordinary tap water its limit of life is about seven days. In investigations by Karlinsky on the anthrax bacillus and the cholera vibrio very similar conclusions were reached. While some observers maintained that the lack of nutriment was the principal cause of the disappearance of pathogenic bacteria, others thought that they succumbed in the struggle with the more hardy non-pathogenic organisms. Recent experiments by Konradi seem to show, however, that in regard to these points current opinion is in the wrong. He has found that instead of dying out in tap water, certain pathogenic bacteria—typhoid bacillus, anthrax bacillus, and staphylococcus aureus—live for a long time, finally killing out all the ordinary water organisms. Thus, in the case of typhoid bacillus, a pure culture resulted in about two months, of anthrax in half that time. The typhoid bacillus lived in tap water at room temperature for 499 days. The practical lesson to be learnt from Konradi's experiments is that when water is once infected it retains its dangerous properties for much longer than has hitherto been supposed.

#### Chemists and Prescribing.

THE attitude of the best class of chemists towards the question of "counter-prescribing" is always more or less apologetic. It is admitted that prescribing does not fall within the legitimate sphere of work of the chemist, but there generally goes with this admission an attempt to show that there is a certain amount of unavoidable prescribing which falls into a chemist's business, and is said to be beneficial to the public. Some of the arguments brought forward by Mr. F. Truman, in a paper read recently to his fellow-chemists at Richmond in support of this thesis, strike us as worthy of comment. In minor ailments he thinks it is not only necessary for the business of the chemist, but for the good of the public, that the chemist should be able to prescribe suitable remedies. Curiously enough, he instances warts as one of these minor ailments which naturally fall to the chemist for treatment. This is rather an unfortunate example, for in the very same number of our contemporary (a) in which we read Mr. Truman's remarks, we find a report of an action against a chemist for injuries to a boy's hand by treating it with nitric acid for warts. Mr. Truman holds, too, that were it not for the treatment by chemists many cases would remain untreated at all until too late. This is possible, but there are probably far more cases where the treatment given by a chemist—in no true sense medical treatment at all—encourages a patient or his friend to do without medical assistance till it is too late for it to be of service. The same number of our contemporary draws attention to a coroner's remarks on this very point. We are, however,

(a) *Pharm. Journ.*, October 22nd, 1904.

quite ready to believe Mr. Truman when he says that the chemist, more frequently than is credited, prescribes a doctor.

#### Sterile Water Anaesthesia.

GREAT as has been the boon conferred on surgical patients by the discovery of general anaesthetics, it would be folly to assert that any anaesthetic yet known is free from drawbacks. They all have their disadvantages and dangers, and till the ideal anaesthetic is found, several of the methods in use at present will each have its appropriate sphere. Gant, the professor of rectal surgery in the New York Post-Graduate School, has just published a third contribution in eighteen months advocating the use of sterile water as a local anaesthetic. He claims that it is safe and trustworthy, and he states that he has adopted it only after trying cocaine and various other agents, which were liable either to produce toxic effects or to be followed by post-operative pain or hæmorrhage. The great point to be observed in using sterile water is to produce distension of the tissues until they become anæmic. To do this no large quantity of water is needed, ten minims to half a drachm being all that is required for small, and a half to four drachms for more extensive operations. An ordinary hypodermic needle is sufficient in the way of apparatus, and though the first injection may cause a little stinging this soon passes off, and the injections can be continued. Effective local anaesthesia is rapidly produced, and no unpleasant complications or sequelæ have followed in his 320 cases in which water injections have been used. Gant claims that he is now able to do in his office scores of operations on patients who would otherwise have had to leave their work for some time and go into hospital. As most of his operations have been in connection with rectal diseases, we think his evidence is particularly significant, as there are no more tender spots than the rectum and the margin of the anus when diseased. Piles, internal and external, fistula, fissure, and prolapsus recti have all been dealt with under simple water distension. Besides these, Gant has done a good variety of other operations, including an exploratory laparotomy, by the same plan. He does not consider that his method is likely to supersede the use of general anaesthetics for all ordinary surgical work, but for small operations he is convinced that no method can touch it, and he warmly recommends surgeons to try it.

#### Surgeon-General Evatt on Irish Medical Schools.

WE have had occasion in the past to differ with Surgeon-General Evatt, the special commissioner of the Irish Medical Association, when he informed the public at large that there was no mechanism in Ireland by which medical practitioners could obtain information on practical points connected with their profession, and we must now again differ with him in respect of his most uncalled-for attack on the Irish Medical schools. After a

(a) *Med. Record*, October 29th, 1904.

public dinner given in his honour last week in Roscommon, Surgeon-General Evatt spoke as follows :—

"They had no idea of the energy and force of English medical education. There they had plenty of money and a string of universities. The position of the Irish schools on the other hand called for the most earnest inquiry. In England and Scotland it was recognised that the training of a doctor demanded money and energy. Oxford had wakened up, and all England was waking up, re-acting against the Irish doctors, whose chances of getting employment in the public service were greatly injured by the want of fuller training and teaching in the Irish schools. In Ireland they wanted efficiency in every branch of the medical service. The doctor ought to be the teacher of humanity in the ways that lead to the betterment of humanity. But for this they required men of energetic and carefully trained character. At the present time the Irish medical schools are hardly mentioned, because they do not take part in research work."

May we ask Surgeon-General Evatt his authority for these statements, which appear to us to constitute a libel on the Irish medical schools? His indictment is all the more dangerous in that it is indefinite and vague. Does he mean to suggest that the Oxford medical school is superior to the Irish schools? Where is it that the Irish schools are never mentioned? It can hardly be where their graduates have gained distinctions, and if it is in places where they have not done so that "we never mention her, her name is never heard," it is not a matter of particular importance, for there are few such places. We notice that Surgeon-General Evatt has been addressing the students of these same Irish medical schools during the past week. Did he when doing so tell them his opinion of their teachers? If he did not do so, why did he not? If the creation of dissatisfaction is the surest way of effecting reform, surely it would be better to create such dissatisfaction at the centre rather than in a country town, where there are none to answer.

#### Twin Spirits.

THERE is not much to be said in favour of the public exhibition of human freaks and monstrosities, but while human nature likes to be surprised and horrified at the same time there will always be showmen ready to cater for this morbid taste. Since the Siamese twins shocked and delighted the British public a good many years ago, there have been many rivals for their fame, but none who have quite attained it. Two—or perhaps we should rather say one—bold candidates have entered the lists in the shape of the Bohemian twins, young ladies of prepossessing appearance joined to each other at the hips. They are twenty years old and not in the least alike, whilst in order to walk they have to pass their arms round each others' waists. An interesting and curious medico-legal question has arisen in connection with their journey to England; and as there appears to be no possible final solution to the problem, it will pro-

bably commend itself warmly to anthropologists, ante-natal pathologists, and counsel learned in law. The point is this: are the twins entitled to travel with one railway ticket? As a practical aid to the discussion, it may be stated that the German railway officials insisted on two tickets being taken, the Belgian authorities were content with one, whilst our own South-Eastern was ungallant enough to follow the Teutonic lead. To psychologists the question of duality or identity of the units that compose the twins should appeal with special attractiveness, and Mr. Rider Haggard's dog will now have to take a back seat, as the question of the hour, with those who are wrapped up in matters concerning thought-transference and telepathy. For ourselves, we only venture to express the hope that the young ladies are good friends; a quarrel leading to mutual estrangement opens up awkward possibilities.

#### The Science Schools in Trinity College, Dublin.

It will be remembered that some eighteen months ago Lord Iveagh made the munificent offer to supply funds for the erection of buildings as schools of science in Trinity College, provided funds for their up-keep were forthcoming from other sources within three years. It was calculated that a sum of £34,000 was necessary for building purposes, and that £78,000, invested at 3½ per cent., would be required for up-keep. For this £78,000 appeal was made to the public, and particularly to graduates of the University. It can hardly be said that the response has been gratifying. Those immediately interested in the College—Fellows and Professors—have contributed generously to the fund, but the sum received from the body of graduates in general is not what might have been expected. Up to the present about sixteen thousand pounds has been received, and this being sufficient for the maintenance of a physical laboratory, the building of the latter is about to be undertaken. We understand that the administration of the fund is to be in the hands of trustees quite independent of the Board of Trinity College, so that those who disapprove of the present oligarchical method of governing the College have no excuse on that ground for refusing to contribute. We are sure that there are many medical graduates of Dublin who will be glad to take the present opportunity of showing their love for "Old Trinity," and we have pleasure in bringing the appeal to their notice.

#### Militant Antivaccinists.

AMONG the minor troubles of the central government in this country the chronic difficulty with the antivaccinists is not the least. But bold and recalcitrant as they are, the antivaccinists confine their methods of warfare with the constituted authorities to the legitimate ones of public meetings and pamphleteering—with an occasional appearance in the law-courts. Not so, however, their *compères* in Brazil. The Congress of that country recently passed a law to enforce compulsory

vaccination, and a commission was appointed to draft the regulations required to administer the enactment. There was considerable public excitement in Rio de Janeiro at the time over the law, which was opposed to popular prejudice, and the premature publication of the regulations set the tinder aflame. In South American States the populace have a very practical way of showing their opinions on matters of public interest, and a riot which almost attained the dignity of a revolution was promptly organised. The Ministry of Industry, when the commission was sitting, was surrounded by the mob, and so threatening was its attitude that the troops were called out and a free fight began. The water-mains were cut the street-lamps destroyed, the trams set on fire, and the telephone wires cut. The rioting continued in spite of repeated charges by the troops, and when night fell it was found that seven persons had been killed and thirty wounded. The next day the disturbances were renewed, but fortunately the authorities were able to get wind of the movements of the ringleaders, and have them arrested. The riot was then suppressed, but not until quite an alarming list of casualties had occurred. After reading of these disturbances we are glad to think that our own antivaccinists, at any rate, employ only hard words in their controversies. And hard words break no bones.

#### Public Libraries and Infectious Diseases.

THE statement so often circulated in the lay press that free libraries spread infectious disease far and wide has created a perennial flutter among those literary dove-cotes. Regarded simply as a place where all sorts and conditions of men, women, and children congregate for the purpose of satisfying the wants of the mind, a process which necessitates touching the same object successively by scores of ungloved and, in many cases, unwashed hands, there is every reason why a public library should be an unfailling source of infectious disease. We have not seen any recently recorded instance of a contagious malady contracted by a visit to a reading-room, but in the event of a person in the desquamating stage of scarlet fever handling a magazine and scattering epidemic scales around him while so occupied it is conceivable that the periodical in question might become a source of infection to others. This is not, however, the fault of the library. Other public buildings are daily exposed to the same risk. The majority of the municipal authorities are now so fully alive to the dangers incurred by spitting, wetting the fingers before turning over the pages of a book or newspaper, in view of the omnipresence of the tubercle bacillus, that in many localities notices prohibitory of such practices are posted up in conspicuous places in the interior of the buildings. The only improvement that might, perhaps, be suggested with a view of further diminishing the risk of infection is the substitution of washable covers for magazines, &c., instead of the leather ones now in use. With regard to the question of infection from books taken home it is

gratifying to note that an inquiry instituted into the subject a few years ago as a result of circularising the medical officers of health in the principal towns possessing public libraries showed that not a single case of infectious disease could be definitely traced to this source.

#### Teaching of Hygiene in Primary Schools.

IN connection with the movement for the teaching of hygiene in primary schools, an influential deputation waited the other day on Dr. Starkie, the Resident Commissioner of National Education in Ireland. Sir William Thomson was the principal spokesman, and he was accompanied by the respective Presidents of the Royal Colleges of Physicians and Surgeons, the Academy of Medicine, and the Leinster Division of the British Medical Association, and other gentlemen. It was strongly pressed on Dr. Starkie that the teaching of hygiene and temperance should be made compulsory in the primary schools throughout the country, and that greater care should be taken to keep school buildings in proper sanitary condition. It was freely admitted by the Resident Commissioner that the rules of the Board as to the sanitary care of school buildings had been quite neglected in the past, and he quoted instances of scandalous mismanagement in this respect. Steps are being taken, however, to stop the grant to any school which shall in future be reported by the Board's inspectors as improperly kept as regards sanitary arrangements. With respect to the teaching of hygiene, Dr. Starkie bound himself to urge on his colleagues the advisability of including it in the new programme of studies as a compulsory subject. The result of the deputation is, on the whole, satisfactory, and it is hoped that before long every child in elementary schools in Ireland will learn something of the value of fresh air and cleanliness, and of the proper care of the human body.

#### Health and Statistics of Ireland.

IT is difficult to pick any crumbs of comfort out of the latest Quarterly Return from Charlemont House. Although the state of the country is good as regards prevalence of disease, yet the birth-rate is low in proportion to the death-rate, and the marriage-rate remains almost stationary. The emigration figures still show an alarming increase, not merely relatively to the estimated population, but in absolute numbers. Thus, the number of emigrants who left Irish shores during the months of July, August and September was 11,784, of whom nearly two-thirds were females. This total is 590 more than in the corresponding quarter of last year, and 1,075 above the average for the third quarter of the past ten years. Compared to the vital rates of England during the last quarter, the Irish birth-rate is 23.3 per 1,000 to 28.1 in England, while the death-rate approaches as close at 14.8 per 1,000 to 15.8 per 1,000. These figures depend in Ireland on the fact that it is the young adults who emigrate at the very time when they should be adding to the birth-rate. The mortality from infectious diseases is somewhat

below the average. Small-pox has appeared in sixteen or more centres during the quarter, and four deaths resulted. Measles had caused less trouble than in previous years, but whooping-cough of a severe type has been more prevalent than usual. Enteric fever has been less prevalent than is usual in the September quarter, though in Belfast it is responsible for thirty-one deaths.

#### Hats or No Hats?

SOME of the lay papers in New York have recently been discussing the question of the effect of hats upon the health. It appears that it was more or less fashionable this year in America to go with the head uncovered, and, as is natural, the hygienic advantages of the custom are being pointed out. It is stated, fairly enough, that the presence of a hat deprives the head of the healthy influences of the light and air, both of which are probably efficacious in maintaining a proper growth of hair. Further, there can be no doubt that a hard hat, such as the ordinary silk or felt hat, encourages the growth of bacteria about the hair by keeping it bathed in a warm, moist atmosphere. Objectors urge that to uncover the head may bring on neuralgia, rheumatism, and other diseases, but this is only liable to occur when one is suddenly exposed to unaccustomed chill. Patients in open-air sanatoria rarely wear head covering, and they rapidly become hardened against the ill-effects supposed to be due to sudden changes of temperature. There is no doubt, of course, that hats may be necessary for protection against the sun, but this, again, is only true where one is exposed to a degree of heat to which, individually or racially, he is unaccustomed. A native of the tropics goes bareheaded with safety where a European would infallibly suffer from heat-stroke. While "hatlessness" in fashionable society is at present little more than a fad, yet it is, on the whole, a healthy one, and we welcome it as part of the same rational view of costume which has rendered light and comfortable head-gear so much in vogue in England during the past few summers.

#### X-Ray Operator as Medical Witness.

THE new science of radiography has given birth to a fresh order of unqualified practice. Persons who hold no medical qualification pose as authorities on dislocation, fractures, and other injuries, not to mention bone diseases, lupus, cancer, rodent ulcer, and conditions open to treatment by the focus-tube. To a great extent the medical profession has itself to thank for having opened the door to this particular kind of competition. From the outset of this new branch of diagnosis we have insisted that medical men should send their cases to properly qualified medical radiographers and not to instrument makers and photographers and other unqualified persons who buy an apparatus and pose as medical advisers. The greatest blame we attach unhesitatingly to hospitals that employ non-medical radiographers. The evil likely to result in the creation of a kind of

hybrid medical practitioner was a week or two since illustrated at a Deptford inquest held upon the body of a child that died under chloroform administered for the purpose of taking a radiogram. Mr. Vezey, the non-medical superintendent of the X-Ray department of the Millar Hospital, was asked by the Coroner whether he thought the rays used on that occasion caused an irritation and affected the child's heart. Instead of referring so highly crucial and technical a question to a medical man, the witness, according to a report in the *Daily Chronicle*, expressed a view that the heart would not be so affected, but that beyond a doubt the X-rays would produce a painful disease if the use extended over several years. Mr. Vezey is well known as the treasurer of the Röntgen Society, and also as an amiable and unassuming student of scientific matters. We venture to think, however, that he is entirely out of place as a witness to medical questions of an extremely complicated nature. The attitude of the Coroner towards his evidence absolutely endorses our view as to the danger likely to arise from the interference of unqualified persons in things that are obviously purely medical.

#### The Wellcome Historical Exhibition.

THE proposed Historical Medical Exhibition has been postponed to a later date than that originally intended. The following announcement to that effect has been received from Mr. Henry S. Wellcome:—

"The response to the announcement of the proposed Historical Medical Exhibition has been beyond my expectations, and this, together with the many valuable suggestions received from leading members of the profession and the trade, at home and abroad, has prompted me to considerably widen its scope. The extent of the work involved renders it impossible to fix a definite date for the exhibition until a later period, announcement of which will be duly made. Although in one sense I regret this delay, it will, on the other hand, enable me to make the exhibit more comprehensive and complete, and to include many objects of exceptional interest that have been promised from different quarters of the globe."
